SOFTWARE DEVELOPMENT PROTOCOLS -- THE MAX MACHINE

Following is a list of "software protocols" -- standards you should use when programming cartridge-based software for the Commodore VIC 20. These protocols standardize copyright notice, use of function keys, keyboard controls and special options.

1. OPENING DISPLAY

The opening display should include the copyright notice (see Number 2) and a program title. If it is known in advance that a program will be sold under different names in different countries, the name of the program may be excluded, but copyright notice must appear. The program should AUTOSTART and launch IMMEDIATELY INTO THE PROGRAM, with the copyright notice shown in the upper lefthand corner briefly, then disappearing as the game begins.

2. COPYRIGHT NOTICE

The proper copyright notice, which must appear in the opening display of all programs, is:

(c) 1982 Commodore Electronics Ltd.

If program memory space is tight, the following alternatives may be used:

(c) 1982 Commodore Elec. Ltd
(c) 1982 Commodore

3. STARTING THE PROGRAM

All cartridge games should run automatically (AUTOSTART) when the computer is first powered up. The protocols for STARTING a cartridge program are:

FROM THE KEYBOARD...use the f1 function key.
FROM THE JOYSTICK...use the fire button.
FROM THE PADDLE.....use the fire button (and
check POT value).

Cartridges which use either joystick or keyboard should start from the fire button, and restart between rounds the same way. Keyboard-only programs should use the f1 key to start or restart. Some programs may require the use of the f1 key to start the program initially, with the fire button used to restart the game between rounds.

~~Paddles and Joysticks.~~ If you're testing for a paddle to start a game, you should also test the POT VALUE to see if there is a paddle being used (not just the pushbutton), otherwise the program might think you're restarting with a joystick, since the paddle pushbutton is the same as "joystick left". If the POT value is not 255 then you have a paddle present.

4. USE OF GAME CONTROLS/PRIORITIES

If your program/game uses a SINGLE JOYSTICK or includes a ONE PLAYER OPTION calling for a single joystick, the program should look to Game Control Port A first and use that port for 1 player programs. MAX joystick is on the righthand of the keyboard and should be used for single player programs.

On the Commodore-64 there are 2 joystick ports on the right side of the computer. Joystick A is the port closest to the back of the machine.

5. SELF-ADJUSTING SCREEN

The "self adjusting" feature of the MAX MACHINE should automatically center the picture on the screen before the program begins. This centering occurs automatically in the MAX.

6. GAMES/HIGH SCORE

All games should record the previous "high score" for that game and display it either between rounds, or in the corner of the screen while the game is being played.

7. GAME "REWARDS"

As a general standard, computer games should include several levels of difficulty (usually as the game progresses) and one or more "reward" rounds which may take the form of a musical or visual display or a "bonus" round with special game action or higher rounds for reaching a higher score, new graphic characters introduced at higher levels, etc. Many games have special "hidden" rewards at higher rounds which prompt the user to play the game over and over again to gain expertise to reach those rounds.

SECTION VI

1. The first group of people who are mentioned in the text are the "people of the land". These are the people who are living in the land and who are the ones who are responsible for the land. They are the people who are the "people of the land" and who are the ones who are responsible for the land.

LHOAH XAM ...
...
...

2000

1. The first step is to identify the problem or goal. This involves understanding the current situation and what needs to be achieved.

2. Next, it is important to gather information and resources. This can include research, consultation with experts, and identifying the tools and materials needed.

3. Once the information is gathered, the next step is to develop a plan. This involves breaking down the goal into smaller, manageable tasks and determining the order in which they should be completed.

4. After the plan is developed, it is time to execute the plan. This involves carrying out the tasks and monitoring progress along the way.

5. Finally, it is important to evaluate the results. This involves comparing the actual outcomes to the original goal and determining whether the plan was successful.

COMODO 64 ASSEMBLER

Commodore 64 assembler is an assembler for the Commodore 64. It is a command-line program that takes source code as input and produces object code as output. The object code can then be loaded into the Commodore 64 and executed. The assembler is written in Commodore 64 assembly language and runs on the Commodore 64.

SAMPLE ASSEMBLER SESSION

The following program is a sample program that demonstrates the use of the Commodore 64 assembler.

1. LOAD "BOOTWALL" ;load editor/loader/DOS wedge
2. RUN ;run the editor/loader/DOS wedge
3. GET "CBM64.SRC" ;load in a source program
4. ;edit your source program
5. PUT "CBM64.SRC" ;save your changes
6. LOAD "ASM.C64" ;load Commodore 64 assembler
7. RUN ;

Note: if you wish to assemble your source code without generating an object file, do not enter a file name when the assembler prompts you for object file name.

COMMODORE 64 ASSEMBLER SYSTEM

The COMMODORE 64 assembler system is an update of the CBM 8032 version*. With the macro assembler and associated support programs, the user can now develop 6510 machine machine code directly on the COMMODORE 64. The assembler requires the 1541 disk drive and optionally a 1525 printer.

Included on the COMMODORE 64 developer's disk are the following programs:

DOS BOOT	boots the DOS wedge (RUN)	
BOOT ALL	boots the editor/loader/DOS wedge (RUN)	
ASM.C64	macro assembler (RUN)	
LOLOAD.C64	loader at \$0800 (RUN)	
HILOAD.C64	loader at \$C800 (SYS 51200)	
EDIT.C64	editor for assembly source (SYS 49152)	
XREF.C64	cross reference for assembler (RUN)	
DOS 5.1	DOS manager (SYS 52224)	
XVM4.8	40 column monitor at \$8000 (SYS 32768)	
XVM4.C	40 column monitor at \$C000 (SYS 49152)	
CBM64DOS.SRC	source code to DOS manager 5.1	
CBM64 TO PET	short form PET emulator	
BYEBYE	screen blank and restore routine.	

The following list shows the differences between old versions of the assembler system and the version for the COMMODORE 64.

Assembler

1. Centronics print option has been removed.
2. The screen is not cleared when the assembler is run.
3. Cannot run xref and object at the same time due to restrictions in the 1541.
4. This assembler has macros.
5. The screen is blanked when printing.

Loaders

1. Loaders print start address and end address of the load. It also prints "." on each record.
2. Loaders reside at \$0801 and \$C800.
3. Editor and loader can be co-resident.

Editor

1. The cold and the break commands have been removed.
2. This version does not scroll. (soon!)

* note: a copy of the CBM 8032 Assembler Development Package User's Manual can be obtained by contacting Stephen Murri at (215) 687-9880.

INTRODUCTION

This manual describes the Assembly Language and assembly process for programs for the MCS-650X series of microprocessors. Several assemblers are available for program development, and while they are all slightly different in detail of use, they are the same in substance.

The process of translating a mnemonic or symbolic form of a computer program to actual machine code is called assembly, and a program which performs the translation is an assembler. The symbols used and rules of association for those symbols are the Assembly Language. In general, one Assembly Language statement will translate into one machine instruction. This distinguishes an assembler from a compiler which may produce many machine instructions from a single statement. An assembler which executes on a computer other than the one for which code is generated is called a cross-assembler. Use of cross-assemblers for program development for microprocessors is common since often a microcomputer system has fewer resources than are needed for an assembler. However, in the case of the Commodore system this is not true. With a floppy disk and printer the system is well suited for software development.

Normally digital computers use the binary number system for representation of data and instructions. Computers understand only ones and zeroes corresponding to an "on" or "off" state. Users, on the other hand, find it difficult to work with the binary number system and hence use a more convenient representation such as octal (base 8), decimal (base 10) or hexadecimal (base 16). Two representations of the MCS-650X operation to "load" information into an "accumulator" are:

10101001 (binary)
A9 (hexadecimal)

An instruction to move the value 21 (decimal) to the accumulator is:

A9 15 (hexadecimal)

Users still find numeric representations of instructions tedious to work with, and hence, have developed symbolic representations. For example, the preceding instruction might be written as:

LDA #21

In this case, LDA is the symbol for A9, Load the Accumulator. A computer program used to translate the symbolic form LDA to numeric form A9 is called an assembler. The symbolic program is referred to as source code and the numeric program is the object code. Only object code can be executed on the processor.

Each machine instruction to be executed has a symbolic name referred to as an operation code (OPCODE). The OPCODE for "store accumulator" is STA. The OPCODE for "transfer accumulator to index X" is TAX. The 56 OPCODES for MCS-650X processors are detailed in Chapter 2. A machine instruction in

Assembly Language consists of an OPCODE and perhaps OPERANDS, which specify the data on which the operation is to be performed.

Instructions may be labelled for reference by other instructions as shown in:

L2 LDA #12

The label is L2, the OPCODE is LDA, and the OPERAND is #12. At least one blank must separate the three parts (fields) of the instruction. Additional blanks are inserted by the assembler for ease of reading. Instructions for the MCS-650X processors have at most one OPERAND and many have none. In these cases the operation to be performed is totally specified by the OPCODE as in CLC (Clear the Carry Bit).

Programming in Assembly Language requires learning the instruction set (OPCODES), addressing conventions for referencing data, the data structures within the processor, as well as the structure of Assembly Language programs. The user will be aided in this by reading and studying the MCS-650X hardware and programming manuals supplied with this development package.

INSTRUCTION FORMAT

Assembler instructions for the MCS-650X assembler are of two basic types according to function:

- . Machine instructions, and
- . Assembler directives

Machine instructions correspond to the 56 operations implemented on the MCS-650X processors. The instruction format is:

(label) (OPCODE) (OPERAND) (comments)

Fields are bracketed to indicate that they are optional. Labels and comments are always optional and many OPCODES such as RTS (Return from Subroutine) do not require OPERANDS. A typical instruction showing all four fields is:

LOOP LDA BETA,X FETCH BETA INDEXED BY X

A field is defined as a string of characters separated by a blank space or tab characters. The list of OPCODES for the MCS-650X processors is shown in Table 1.

A label is an alphanumeric string of from one to six characters, the first of which must be alpha. A label may not be any of the 56 OPCODES, nor any of the special single characters, i.e. A, S, P, X or Y. These special characters are used by the assembler to reference the:

- . Accumulator (A)
- . Stack pointer (S)
- . Processor status (P)
- . Index registers (X and Y)

A label may begin in any column provided it is the first field of an instruction. Labels are used on instructions as branch targets and on data elements for reference in OPERANDS.

Table 1. MCS-650X Microprocessor Instruction Set - OPCODES

ADC	Add with Carry to Accumulator	JSR	Jump to New Location Saving Return Address
AND	"AND" to Accumulator	LDA	Transfer Memory to Accumulator
ASL	Shift Left One Bit (Memory or Accumulator)	LDX	Transfer Memory to Index X
BCC	Branch On Carry Clear	LDY	Transfer Memory to Index Y
BCS	Branch on Carry Set	LSR	Shift One Bit Right (Memory or Accumulator)
BEQ	Branch on Zero Result	NOP	Do Nothing - No Operation
BIT	Test Bits in Memory with Accumulator	ORA	"OR" Memory with Accumulator
BMI	Branch on Result Minus	PHA	Push Accumulator on Stack
BNE	Branch on Result not Zero	PHP	Push Processor Status on Stack
BPL	Branch on Result Plus	PLA	Pull Accumulator from Stack
BRK	Force an Interrupt or Break	PLP	Pull Processor Status from Stack
BVC	Branch on Overflow Clear	ROL	Rotate One Bit Left (Memory or Accumulator)
BVS	Branch on Overflow Set	ROR	Rotate One Bit Right (Memory or Accumulator)
CLC	Clear Carry Flag	RTI	Return From Interrupt
CLD	Clear Decimal Mode	RTS	Return From Subroutine
CLI	Clear Interrupt Disable Bit	SBC	Subtract Memory and Carry from Accumulator
CLV	Clear Overflow Flag	SEC	Set Carry Flag
CMP	Compare Memory and Accumulator	SED	Set Decimal Mode
CPX	Compare Memory and Index X	SEI	Set Interrupt Disable Status
CPY	Compare Memory and Index Y	STAA	Store Accumulator in Memory
DEC	Decrement Memory by One	STX	Store Index X in Memory
DEX	Decrement Index X by One	STY	Store Index Y in Memory
DEY	Decrement Index Y by One	TAX	Transfer Accumulator to Index X
EOR	Exclusive-or Memory with Accumulator	TAY	Transfer Accumulator to Index Y
INC	Increment Memory by One	TSX	Transfer Stack to Index X
INX	Increment X by One	TXA	Transfer Index X to Accumulator
INY	Increment Y by One	TYA	Transfer Index Y to Accumulator
JMP	Jump to new Location		
TXS	Transfer Index X to Stack Register		

The OPERAND portion of an instruction specifies either an address or a value. An address may be computed by expression evaluation and the assembler allows considerable flexibility in expression formation. An Assembly Language expression consists of a string of names and constants separated by operators +, -, *, and / (add, subtract, multiply, and divide). Expressions are evaluated by the assembler to computer OPERAND addresses. Expressions are evaluated left to right with no operator precedence and no parenthetical grouping. Note that expressions are evaluated at assembly time and not execution time.

Any string of characters following the OPERAND field is considered a comment and is listed, but not further processed. If the first non-blank character of any record is a semi-colon (;), the record is processed as a comment. On the instructions which require no OPERAND, comments may follow the OPCODE. At least one separating character (space or horizontal tab) must separate the fields of an instruction.

There are twelve assembler directives used to reserve storage and direct information to the assembler. Eleven have symbolic names with a period as the first character. The twelfth, a symbolic equate, uses an equals sign (=) to establish a value for a symbol. A list of the directives are given below and their use is explained in a later section.

.IFE	.BYTE	.WORD	.DBYTE	.PAGE	.SKIP
.IFN	.OPT	.END	.FILE	.LIB	*=

Labels and symbols other than directives may not begin with a period.

A typical MCS-650X assembler program segment is shown in Table 2. This table is presented primarily to show the form of the information output by the assembler.

SEGMENT OF AN MCS-650X PROGRAM

LINE#	LOC	CODE	LINE

SYMBOLIC

Perhaps the most common OPERAND addressing mode is the symbolic form as in:

```
LDA BETA      PUT BETA VALUE IN ACCUMULATOR
```

In the example BETA references a byte in memory that is to be loaded into the accumulator. BETA is an address at which the value is located. Similarly, in the instruction

```
LDA ALPHA+BETA
```

the address ALPHA+BETA is computed by the assembler and the value at the computed address is loaded into the accumulator.

Memory associated with the MCS-650X processors is segmented into pages of 256 bytes each. The first page, page zero, is treated differently by the assembler and by the processor for optimization of memory storage space. Many of the instructions have alternate operation codes if the OPERAND address is in page zero memory. In those cases the address requires only one byte rather than the normal two. For example, if BETA is located at the byte 4B in page zero memory, then the code generated for

```
LDA BETA
```

is A5 B4. This is called page zero addressing. If BETA is at 010113C in memory page one the code generated is AD 3C 10. This is an example of absolute addressing. Thus, to optimize storage and execution time, a programmer should design with data areas in page zero memory whenever possible. Note that the assembler makes decisions on which form to use based on OPERAND address computation.

CONSTANTS

Constant values in Assembly Language can take several forms. If a constant is other than decimal a prefix character is used to specify type.

\$	(Dollar sign) specifies hexadecimal
@	(Commercial at) specifies octal
%	(Percent) specifies binary
'	(Apostrophe) specifies an ASCII literal character in immediate instructions

The absence of a prefix symbol indicates decimal value. In the statement

```
LDA BETA+5
```

the decimal number 5 is added to BETA to compute the address. Similarly;

```
LDA BETA+$5F
```

denotes that the hexadecimal value 5F is to be added to BETA for the address computation.

The immediate mode of addressing is signified by a # (a pounds

sign on some printers) followed by a constant.

Example: LDA #2

specifies that the decimal value 2 is to be put into the accumulator. Similarly;

LDA #'G

will load the ASCII character G into the accumulator.

Immediate mode addressing always generates two bytes of machine code, the OPCODE and the value to be used as OPERAND. Note that constant values can be used in address expressions and as values in immediate mode addressing. They can also be used to initialize locations as explained in a later section on assembler directives.

RELATIVE

There are 8 conditional branch instructions available to the user.

Example: BEQ START IF EQUAL BRANCH TO START

which might typically follow a compare instruction. If the values compared are equal a transfer to the instruction labelled START is made. The branch address is a one byte positive or negative offset which is added to the program counter during execution. At the time the addition is made the program counter is pointing to the next instruction beyond the branch instruction. Thus, a branch address must be within 127 bytes forward or 128 bytes backward from the conditional branch target instruction. An error will be flagged at assembly time if a branch target falls outside the bounds for relative addressing. Relative addressing is not used for any other instructions.

IMPLIED

Twenty-five instructions such as TAX (Transfer Accumulator to Index X) require no OPERAND and hence are single byte instructions. Thus, the OPERAND addresses are implied by the operation code.

Four instructions, ASL, LSR, ROL and ROR are special in that the accumulator, A, can be used as an OPERAND. In this special case, these four instructions are treated as implied mode addressing and only an operation code is generated.

INDEXED INDIRECT

In this mode the OPERAND address is a location in page zero memory which contains the address to be used as an OPERAND.

Example: LDA (BETA,X)

The parentheses around the OPERAND indicates indirect mode. In the above example the value in index register X is added to BETA. That sum must reference a location in page zero memory. During execution the high order byte of the address is ignored, thus forcing a page zero address. The two bytes starting at

that location in page zero memory are taken as the address of the OPERAND. For purposes of illustration assume the following:

BETA is 12
X contains 4
Locations 0017 and 0016 are 01 and 25
Location 0125 contains 37

Then $BETA + X$ is 16, the address at location 16 is 0125. the value at 0125 is 37, and hence, the instruction `LDA (BETA,X)` loads the value 37 into the accumulator. This form of addressing is shown in the following illustration.

INDIRECT INDEXED

Another mode of indirect addressing uses index register Y and is illustrated by:

`LDA (GAMMA),Y`

In this case, GAMMA references a page zero location at which an address is to be found. The value in index Y is added to that address to compute the actual address of the OPERAND. Suppose for example that:

GAMMA is 38 (hexadecimal)
Y contains 7
Locations 0039 and 0038 are 00 and 54
Location 005B contains 126

Then the address at 38 is 0054 and 7 is added to this giving an effective address 005B. The value at 005B is 126 which is loaded into the accumulator.

In indexed indirect, the index X is added to the OPERAND prior to the indirection. The indirect indexed, the indirection is done and then the index Y is added to compute the effective address. Indirect mode is always indexed except for a JMP instruction which allows an absolute indirect address as

exemplified by JMP (DELTA) which causes a branch to the address contained in locations DELTA and DELTA+1. The indexed indirect mode of addressing is shown in the following illustration.

ASSEMBLER DIRECTIVES

There are twelve directives used to control the assembly process, define values or initialize memory locations. Assembler directives always appear in the OPCODE field of an instruction and thus might be considered as assembly time OPCODES instead of execution time OPCODES. The directives are:

```
.IFE    .BYTE    .WORD    .LIB    .DBYTE    .OPT
.IFN    .PAGE    .SKIP    .FILE    * = or =    .END
```

All directives which are preceded by the period may be abbreviated to the period and three characters if desired eg, .BYT.

.BYTE is used to reserve one byte of memory and load it with a value. The directive may contain multiple OPERANDS which will store values in consecutive bytes. ASCII strings may also be generated by enclosing the string with quotes.

```
HERE    .BYTE 2
THERE    .BYTE 1, $F, @3, $101, 7
ASCII    .BYTE 'ABCDEFH'
```

Note that numbers may be represented in the most convenient form. In general, any valid MCS650X expression which can be resolved to eight bits may be used in this directive. If it is desired to include a quote in an ASCII string, this may be done by inserting two quotes in the string;

```
.BYTE 'JIM'S CYCLE'
```

could be used to print:

```
JIM'S CYCLE
```

.WORD is used to reserve and load two bytes of data at a time. Any valid expression, except for ASCII strings, may be used in the OPERAND field.

```
HERE    .WORD 2
THERE    .WORD 1, $FF03, @3
WHERE    .WORD HERE, THERE
```

The most common use for .WORD is to generate addresses as shown in the above example labelled "WHERE" which stores the 16 bit addresses of "HERE" and "THERE". Addresses in the MCS-650X are fetched from memory in the order low-byte and high-byte, therefore, .WORD generates the values in this order. The hexadecimal portion of the example (\$FF03) would be stored 03,FF. If this order is not desired, use .DBYTE rather than .WORD.

.DBYTE is exactly like .WORD except the bytes are stored in high-byte, low-byte order.

```
.DBYTE    $FF03
```

will generate FF,03. Thus, fields generated by .DBYTE may not

be used as indirect addresses.

Equal (=) is the EQUATE directive and is used to reserve memory locations, reset the program counter (*), or assign a value to a symbol.

HERE	==*+1	reserve one byte
WHERE	==*+2	reserve two bytes
*=\$200		set program counter
NB=8		assign value
MB=NB+%101		assign value

The = directive is very powerful and can be used for a wide variety of purposes.

Expressions must not contain forward references or they will be flagged as an error.

Example: * = C + D - E + F

would be legal if C, D, E and F are all defined, but would be illegal if any of the variables were a forward reference. Note also that expressions are evaluated in strict left to right order.

.PAGE is used to cause an immediate jump to top of page and may also be used to generate or reset the title printed at the top of page.

.PAGE	'THIS IS A TITLE'
.PAGE	
.PAGE	'NEW TITLE'

If a title is defined, it will be printed at the top of each page until it is redefined or cleared. A title may be cleared with:

.PAGE ' '.

.SKIP is used to generate blank lines in a listing. The directive will not appear but its position may be found in a listing, since it is treated as a valid input "card" and the card number printed on the left side of the listing will jump by two when the next line is printed.

.SKIP	2	skip two blank lines
.SKIP	3*2-1	skip five lines
.SKIP		skip one line

.OPT is the most powerful directive and is used to control the generation of output fields, listings and expansion of ASCII strings in .BYTE directives.

.OPT	ERRORS, LIST, MEMORY, GENERATE
.OPT	NOE, NOL, NOM, NOG

Also valid is:

.OPT ERR

Default settings are:

.OPT MEM, LIST, ERR, NOGEN

Here are descriptions for each of the OPERANDS:

RORS [NO ERRORS]:

Used to control creation of a separate error file. The error file contains the source line in error and the error message. This facility is normally of greatest use to time-sharing users who have limited print capacity. The error file may be turned on and examined until all errors have been corrected. This listing file may then be examined. Another possibility is to run with:

.OPT ERRORS, NOLISTING

until all errors have been corrected, and then make one more run with:

.OPT NOERRORS, LISTING

LIST [NOLIST]:

Used to control the generation of the listing file which contains source input, errors and warnings, code generation, symbol table and instruction count if enabled.

MEMORY [NOMEMORY]:

Used to control generation of the memory file, which is used as an interface between the assembler and the simulator and various loader programs. The memory file contains information about symbols, line numbers and code generation, and is described in detail elsewhere in this document.

GENERATE [NOGENERATE]:

Used to control printing of ASCII strings in the .BYTE directive. The first two characters will always be printed, and subsequent characters will be printed (normally two bytes per line), if GENERATE is used.

.END should be the last statement in a file and is used to signal the physical end of the file. Its use is optional, but highly recommended for program documentation.

NOTE: The symbol table will not be generated until a .END is found.

.LIB directive allows the user to construct control files containing this directive which inserts the module named into the assembly. When the assembler encounters this directive, it temporarily ceases reading source code from the file containing it and starts reading from the file named on the .LIB. Processing of the original source file resumes when end-of-file (EOF) or .END is encountered in the library file. The control file containing the .LIB can contain other assembler directives to turn the listing function on and off etc..

A library file called by a LIB may not contain another .LIB, but it may contain a .FIL.

.FIL terminates assembly of the file containing it and transfers source reading to the file named in the OPERAND. There are no restrictions on the number of files which may be linked by .FIL directives. Caution should be exercised when using this directive to ensure that no circular linkages are created. An assembler pass can only be terminated by (EOF) or .END directive.

The following is an example of .LIB control and .FIL control. This example is extensive and it should not be taken verbatim but used as a source of ideas.

.IFE / .IFN

Conditional Assembly Directives, these allow the same source file to be used to generate different versions of the final code, for different machines. The syntax is the same for both :-

```
.IFE expression >
    Code to be assembled
<
```

In this case IF expression equals zero assemble the code between the > and <. The code to be assembled must start on a new line after the <IF, the < must be the first symbol on a line.

.IFN will cause the code between the > and < to be assembled if expression is not zero.

```
Eg.  MEM = 8
      COLS = 40
      * = $3B00 ;DEFAULT START ADDRESS
      WIDTH = 40 ;DEFAULT SCREEN WIDTH
      IFE MEM-8 >
      * = $1B00 ;START FOR 8K PET
      <
      .IFN COLS-40 >
      WIDTH = 80 ;80 COLUMNS ON SCREEN
      <
```

In this example the program counter (*) would be set to \$1B00 and width would be set at 80 (cols-40 = 0)

OUTPUT FILES

There are three output files generated by the assembler. Each file is optional through the use of the .OPT assembler directive. The listing file contains the program list, and symbol table. The error file contains all error lines and errors. The error file is included in the listing file. The interface file contains the object code for the loader.

LISTING FILE

The listing file will be produced unless the NOLIST option is used on the .OPT assembler directive. This file is made up of two sections: Program, and Symbol Table.

Program

This listing will always be produced unless the NOLIST option is selected. It contains the source statements of the program along with the assembled code. Errors and warnings appear after erroneous statements. An explanation of error codes are presented in part B. A count of the errors and warnings found during the assembly are presented at the end of the program.

Symbol Table

The symbol table will always be produced unless the NOSYM option is used. It contains a list of all symbols used in the program, and their addresses.

INTERFACE FILE

The format for the first and all succeeding records, except for the last record, is as follows:

```
; nln0 a3a2ala0 (dld0)1 (dld0)2 x3x2x1x0
```

Where the following statements apply:

1. All characters (n,a,d,x) are the ASCII characters 0 through F, each representing a hexadecimal digit.
2. ; is a record mark indicating the start of a record.
3. nln0 = the number of bytes of data in this record.
(in hexadecimal). Each pair of hexadecimal characters (dld0) represents a single byte in the record.
4. a3a2ala0 = the hexadecimal starting address for the record.
a3 represents address bits 15 thru 12, etc..
The 8-bit byte represented by (dld0)1 is stored in address a3a2ala0; (dld0)2 is stored in (a3a2ala0) + 1, etc.

5. (dld0) = two hexadecimal digits representing an 8-bit byte of data. (dl = high-order 4 binary bits and d0 = low-order 4-bits). Maximum of 18 (Hex) or 24 (decimal) bytes of data per record is permitted.

6. x3x2x1x0 = record check sum. This is the hexadecimal sum of all characters in the record, including the nln0 and a3a2ala0, but excluding the record mark and the check sum of characters. To generate the check sum, each byte of data (represented by two ASCII characters) is treated as 8 binary bits. The binary sum of these 8-bit bytes is truncated to 16 binary bits (4 hexadecimal digits) and is then represented in the record as four ASCII characters (x3x2x1x0).

The format for the last record in a file is as follows:

; 00 c3c2clc0 x3x2x1x0

1. ; 00 = zero bytes of data in this record. This identifies this as the final record in a file.
2. c3c2clc0 = the total number of records (in hexadecimal) in this file, NOT including the last record.
3. x3x2x1x0 = check sum for this record.

ERROR LIST

Error messages are given in the program listing accompanying statement in error. The following is a list of all error messages which might be produced during assembly.

**A,X,Y,S,P RESERVED

A label on a statement is one of the five reserved names (A,X,Y,S and P). They have special meaning to the assembler and therefore cannot be used as labels. Use of one of these names will cause this error message to be printed and zero bytes to be generated for the statement. The label does not get defined and will appear in the symbol table as an undefined variable. Reference to such a label elsewhere in the program will cause error messages to be printed as if the label were never declared.

HOW TO AVOID: Don't use A, X, Y, S or P as a label to a statement.

**A MODE NOT ALLOWED

Following a legal OPCODE, and one or more spaces, is the letter A followed by one or more spaces. The assembler is trying to use the accumulator (A = accumulator mode) as the OPERAND. However, the OPCODE in the statement is one which does not allow reference to the accumulator. Check for a statement labelled A (an illegal statement), which this statement is referencing. If you were trying to reference the accumulator, look up the valid OPERANDS for the OPCODE used.

**INVALID ADDRESS

An address referred to in an instruction, or in one of the assembler directives (.BYTE, .DBYTE, .WORD), is invalid. In the case of an instruction, the OPERAND that is generated by the assembler must be greater than or equal to zero, and less than or equal to \$FFFF (2 bytes long). (This excludes relative branches which are limited to +/- 127 from the next instruction.) If the OPERAND generates more than two bytes of code or is less than zero, this error message will be printed. For a .BYTE each OPERAND is limited to one byte, and for a .WORD each OPERAND is limited to two bytes. All must be greater than or equal to zero.

This validity is checked after the OPERAND is evaluated. Check for values of symbols used in the OPERAND field (see the symbol table for this information).

**FORWARD REFERENCE

The expression on the right side of an equals sign contains a symbol that has not been defined previously. One of the operation of the assembler is to evaluate expressions or labels, and assign addresses or values to them. The assembler processes the input values sequentially, which means that all of the symbolic values that are encountered fall into two classes--already defined values and not previously encountered values. The assembler assigns defined values and builds a table of undefined values. When a previously used value is

discovered, it is substituted into the table and the assembler processes all of the input statements a second time using currently defined values.

A label or expression which uses a yet undefined value is considered to be referenced forward to the to-be-defined value.

To allow for conformity of evaluating expressions, this assembler allows for one level of forward reference so that the following code is allowed.

Card Sequence	Label	Opcode	Operand
100		BNE	New One
200	New One	LDA	#5

But the following is not allowed:

Card Sequence	Label	Opcode	Operand
100		BNE	New One
200	New One		Next + 5
300	Next	LDA	#5

This feature should not disturb the normal use of labels as the cure for this error

Card Sequence	Label	Opcode	Operand
100		BNE	New One
300	Next	LDA	#5
301	New One		Next + 5

is very simple and always solves the problem.

This error may also mean that the value on the right side of the = is not defined at all in the program; in which case, the cure is the same as for undefined values.

The assembler cannot process more than one computed forward reference. All expressions with symbols that appear on the right side of any equal sign must refer only to previously defined symbols for the equate to be processed.

**ILLEGAL OPERAND TYPE

After finding an OPCODE that does not have an implied OPERAND, the assembler passes the OPERAND field (the next non-blank field following the OPCODE) and determines what type of OPERAND it is (indexed, absolute, etc.). If the type of OPERAND found is not valid for the OPCODE, this error message will be printed.

Check to see what types of OPERANDS are allowed for the OPCODE and make sure the form of the OPERAND type is correct (see the section on addressing modes).

Check for the OPERAND field starting with a left paren. If it is supposed to be an indirect OPERAND, recheck the correct format for the two types available. If the format was wrong (missing right paren or index register), this error will be printed. Also check for missing or wrong index registers in an indexed OPERAND (form: expression, index register).

**IMPROPER OPCODE

The assembler searches a line until it finds the first non-blank character string. If this string is not one of the 56 OPCODES it assumes it is a label and places it in the symbol table. It then continues parsing for the next non-blank character string. If none are found, the next line will be read in and the assembly will continue. However, if a 2nd field is found it is assumed to be an OPCODE (since only one label is allowed per line). If this character string is not a valid OPCODE, the error message is printed.

This error can occur if OPCODES are misspelled, in which case the assembler will interpret the OPCODE as a label (if no label appears on the card). It will then try to assemble the next field as the OPCODE. If there is another field, this error will be printed.

Check for a misspelled OPCODE or for more than one label on a line.

**CAN'T EVAL EXPRESSION

In evaluating an expression, the assembler found a character it couldn't interpret as being part of a valid expression. This can happen if the field following an OPCODE contains special characters not valid within expressions (eg parentheses). Check the OPERAND field and make sure only valid special characters are within a field (between commas).

**INDEX MUST BE X OR Y

After finding a valid OPCODE, the assembler looks for the OPERAND. In this case, the first character in the OPERAND field is a left paren. The assembler interprets the next field as an indirect address which, with the exception of the jump statement, must be indexed by one of the index registers, X or Y. In the erroneous case, the character that the assembler was trying to interpret as an index register was not X or Y and the error was printed.

Check for the OPERAND field starting with a left paren. If it is supposed to be an indirect OPERAND, recheck the correct format for the two types available. If the format was wrong (missing right paren or index register), This error will be printed. Also check for missing or wrong index registers in an indexed OPERAND (form: expression, index register).

**LABEL START NEED A-Z

The first non-blank field is not a valid OPCODE. Therefore, the assembler tried to interpret it as a label. However, the first character of the field does not begin with an alphabetic character and the error message is printed.

Check for an unlabelled statement with only an OPERAND field that does start with with a special character. Also check for illegal label instruction.

**LABEL TOO LONG

All symbols are limited to six characters in length. When parsing, the assembler looks for one of the separating characters to find the end of a label or string. If other than one of these separators is used, the error message will be printed providing that the illegal separator causes the symbol to extend beyond six characters in length. Check for no spacing between labels and OPCODES. Also check for a comment card with a long first word that doesn't begin with a semicolon. In this case the assembler is trying to interpret part of the comment as a label.

**NON-ALPHANUMERIC

Labels are made up of from one to six alphanumeric digits. The label field must be separated from the OPCODE field by one or more blanks. If a special character or other separator is between the label and the OPCODE, this error message might be printed.

The 56 valid OPCODES are each three alphabetic characters. They must be separated from the OPERAND field (if one is necessary) by one or more blanks. If the OPCODE ends with a special character (such as a comma), this error message will be printed.

In the case of a lone label or an OPCODE that needs no OPERAND, they can be followed directly by a semicolon to denote the rest of the card as a comment (use of a semicolon tabs the comment out to the next tab position).

**DUPLICATE SYMBOL

The first field on the card is not an OPCODE so it is interpreted as a label. If the current line is the first line in which that symbol appears as a label (or on the left side of an equals sign), it is put in the symbol table and tagged as defined in that line. However, if the symbol has appeared as a label, or on the left of an equate, prior to the current line, the assembler finds the label already in the symbol table. The assembler does not allow redefinitions of symbols and will, in this case, print the error message.

**INDIRECT OUT OF RANGE

An indirect address is recognized by the assembler by the parentheses that surround it. If the field following an OPCODE has parens around it, the assembler will try to assemble it as an indirect address. If the OPERAND field extends into absolute (is larger than 255 - one byte), this error message will be printed.

This error will only occur if the OPERAND field is in correct form (ie an index register following the address), and the address field is out of page zero. To correct this, the address field must refer to page zero memory.

**PC NEGATIVE-RESET 0

An assembled program is loaded into core from position 0 to 64K (65535). This is the extent of the machine. Instructions can only refer to up to 2 bytes of information. Because there is (such a thing as negative memory, an attempt to reference a negative position will cause this error and the program counter (or pointer to the current memory location), will be reset to 0.

When this error occurs, the assembler continues assembling the code with the new value of the program counter. This could cause multiple bytes to be assembled into the same locations. Therefore, care should be taken to keep the program counter within the proper limits.

**RAN OFF END OF CARD

This error message will occur if the assembler is looking for a needed field and runs off the end of the card (or line image) before the field is found. The following should be checked for: a valid OPCODE field without an OPERAND field on the same card: an OPCODE that was thought to take an implied OPERAND, which in fact needed an OPERAND: an ASCII string that is missing the closing quote (make sure any embedded quotes are doubled - to have a quote in the string at the end, there must be 3 quotes - 2 for the embedded quote and one to close off the string); a comma at the end of the OPERAND field indicates there are more OPERANDS to come: if there aren't other OPERANDS, the assembler will run off the card looking for them.

**BRANCH OUT OF RANGE

All of the branch instructions (excluding the two jumps), are assembled into 2 bytes of code. One byte is for the OPCODE and the other for the address to branch to. To allow a forward or backward branch, this branch is taken relative to the beginning of the next instruction, according to the address byte. If the value of the byte is 0-127 the branch is forward; if the value is 128-255 the branch is backward. (A negative branch is in 2's complement form). Therefore, a branch instruction can only branch forward or backward 127 bytes relative to the beginning of the next instruction. If an attempt is made to branch further than these limits, the error message will be printed.

**UNDEFINED DIRECTIVE

All assembler directives begin with a period. If a period is the first character in a non-blank field the assembler interprets the following character string as a directive. If the character string that follows is not a valid assembler directive, this error message will be printed.

Check for a misspelled directive, or a period at the beginning of a field that is not a directive.

**UNDEFINED SYMBOL

This error is generated by the second pass. If, in the first pass the assembler finds a symbol in the OPERAND field (the field following the OPCODE or an equals sign), that has not been defined yet, that symbol is flagged for interpretation by pass two. If the symbol is defined (shows up on the left of an equate or as the first non-blank field in a statement), pass one will define it and enter it in the symbol table. Then a symbol in an OPERAND field before the definition will be defined with a value when pass two assembles it. In this case the assembly process can be completed.

However, if pass one doesn't find the symbol as a label or on the left of an equate, it never enters it in the symbol table as a defined symbol. When pass two tries to interpret the OPERAND field this type of symbol is in, there is no value for the symbol and the field cannot be interpreted. Therefore, the error message is printed with no value for the OPERAND.

This error will also occur if a saved symbol A, X, Y, S or P, is used as a label and referred to elsewhere in the program. On the statement that references the saved symbol, the assembler sees it as a symbol that has not been defined.

Check for use of saved symbols, misspelled labels or missing labels to correct this error.

NOTE:

When the assembler finds an expression (whether it is in an OPERAND field or on the right of an equals sign) it tries to evaluate the expression. If there is a symbol within the expression that hasn't been defined yet, the assembler will flag it as a forward reference and wait to evaluate it in the second pass. If the expression is on the right side of an equal sign, the forward reference is a severe error and will be flagged as such. However, if the expression is in an OPERAND field of a valid OPCODE, the first pass will set aside 2 bytes for the value of the expression and flag it as a forward reference. When the 2nd pass fills in the value of the expression, and the value of the expression is one byte long ie >256, the instruction is one byte longer than required, because the forward reference to page zero memory wastes one byte of memory - the extra one that was saved, because, during the first pass, the assembler didn't know how large the value was, so had to save for the largest value - two bytes.

COMMODORE 64 MONITORS

(XVM4.8 and XVM4.C)

The Commodore 64 monitors are essentially the same as VICMON except for the following considerations:

- o To load the appropriate monitor enter:

```
LOAD "XVM4.8",8,1 (monitor at $8000) SYS 32768 or  
LOAD "XVM4.C",8,1 (monitor at $C000) SYS 49152
```

- o There is no WALK command.

- o There is no TRACE command.

- o In order to protect page zero from destruction, you must execute an E (enable) command before branching to your code with a G command. For example:

Your code is constructed at C100. Before executing a G C100 command, type E C000 (or any other safe area of memory to save page zero). The monitor will use the specified location as a temporary storage area for page 0. When a B (breakpoint) command is encountered in your code, the monitor will restore page 0.

- o After exiting from the monitor, perform a cold start by entering:

SYS 64738

Most programs will remain untouched.

THE DOS WEDGE
(DOS 5.1)

This program is an aid to the Commodore 64 user. When the program is operating, the user may enter disk commands and interrogate the error channel without using BASIC commands.

When the wedge program is running it is "wedged" into the operating system and BASIC interpreter. Thus the program can trap keyboard input before BASIC can see it.

The following is a list of DOS 5.1 commands:

>I0	Initialize drive 0.
>S0:S*	Scratch all files on drive 0 that start with the letter "S".
>\$0	Read the directory on drive 0 and print it to the screen. (This does not destroy programs in memory.)
>\$0:BASIC*	Read the directory on drive 0 and search for filenames starting with BASIC.
>(RETURN)	Interrogate the error channel and print error message on screen.
>#9	Change to device 9 etc.
>Q	Exit DOS wedge.
/ASM.C64	Load the program named "ASM.C64" (LOAD "ASM.C64",8).
↑ASM.C64	Load then run the program named "ASM.C64.
%PADDLE2	Load the program named "PADDLE2" without relocating. (LOAD "PADDLE2",8,1).
←PADDLE2	Save the program named "PADDLE2".

The following list shows differences between old versions of the DOS wedge and DOS 5.1:

- o % command loads without relocating.
- o Commands can be used in a program.
- o DOS 5.1 pulls filename from quotes and ignores the rest of line.
- o Commands do not have to start in column 1.
- o DOS 5.1 does not auto relocate.
- o Arrow left is save command.
- o >#9 changes to device 9, etc.
- o >Q exits DOS 5.1.

UNIVERSAL WEDGE

This program is an aid to the disk user. When the program is operating, the user may enter disk commands and interrogate the disk error channel without using BASIC commands.

When the wedge program is running it is 'wedged' into the operating system and BASIC interpreter. Thus the program can trap keyboard input before BASIC sees it. This is done by linking into the CHRGET routine in page zero.

The operation of the wedge program is accomplished using three commands that are typed in the first character position of a line. The greater-than symbol (>) is used to print the directories, send commands and read the error channel. The following examples illustrate the usage of the > command:

>I0	Initialize drive 0
>S1:S*	Scratch all files on drive one that start with the letter S
>\$1	Read the directory on drive 1 and print it to the PET screen
>\$0:BASIC*	Read the directory on drive 0 and search for filenames starting with the string 'BASIC'

The most notable attribute about this method of reading the directory is that it does not destroy programs in memory so you may examine the directory at any time.

The third use of the > command is interrogation of the disk error channel. This is done by typing:

>(RETURN)

the computer responds by printing the error message on the screen. This does the same thing as the following BASIC program:

```
10 OPEN15,8,15
20 INPUT#15,A,B$,C,D
30 PRINTA;B$;C;D
```

NOTE: After a cold start, do not attempt to read the error channel before sending a command.

Business keyboard users may substitute the @ (commercial at) symbol in place of >.

The second command is the slash command. It performs the same function as the BASIC 'LOAD' with a simplified format:

/ASSEMBLER

The above command loads the program named 'ASSEMBLER'. This does the same thing as the following BASIC command.

LOAD"ASSEMBLER",8

The third program is the LOAD/RUN command. This command is implemented using the up-arrow key ↑.

(↑HURKLE

This example would load then run the program HURKLE.

The wedge program is the first program on the development disk, thus it may be loaded with the LOAD"**,8. This command causes an automatic initialization on Drive 0 when executed as the first disk command after a cold start.

INSTRUCTIONS FOR THE MINI-EDITOR

The MINI-EDITOR is included on the diskette supplied with this manual. There are two versions; EDITOR16K and EDITOR32K, used in 16K and 32K machines respectively. The only difference between the two versions is the load point.

The editor is used to enter and modify source files for the assembler. The editor retains all of the features of the screen editor plus; automatic line numbering, find, change, delete with range, and renumber. Other commands include get, put, break, kill, and format. All of the commands are detailed in the summary at the end of this appendix.

This is a line number oriented editor but with the functions of the screen editor it can be considered to have a character mode which includes the lines appearing on the screen. The editor commands operate in a similar fashion to the commands already existing in the computer's BASIC. There are several example files included on the diskette with the editor. Users would be well advised to try out the editor on these files in order to familiarize themselves with the commands.

The data files on which the assembler operates are ASCII characters with each line terminated by a carriage return. The only restriction on data files is in naming. Due to the method in which the assembler parses, you are not allowed spaces in filenames. The files are sequential and must be terminated by a zero byte \$00.

LOADING THE MINI-EDITOR

The editor can be loaded with the wedge load command or with a BASIC load command:

```

/EDITOR32K    or
LOAD"EDITOR16K",8

```

To initiate the editor use the SYS command. The editor is started with the following commands, SYS7*4096 for the 32K version, and SYS3*4096 for the 16K editor. After typing the SYS command the editor will respond with the message 'MINI-EDITOR V121679'. At this point type a NEW command to clear the text pointers. You are now ready to edit assembler source files.

OPERATION OF THE MINI-EDITOR

When the MINI-EDITOR is in operation any statement typed:

```

10 FOR I=1 TO 10

```

will not be tokenized. Thus, you cannot type a BASIC line with the editor turned on. To avoid the above problem you must disable the editor with the 'KILL' command or reset to start clean.

Source files are loaded with the 'GET' command. As the file is loaded the editor adds line numbers. The editor starts its numbering at 1000. After editing your file, ensure that the

last line is a .FILE or a .END assembler directive. Then save your file on disk with the 'PUT' command.

The repeat key is enabled by typing (return). All of the keys on the keyboard will repeat when held down for more than one-half of a second. The repeat function is still operational after the editor has been killed. To disable the repeat function type: SHIFT-RUN/STOP followed by RUN/STOP (for version 2.0 BASIC). Type LOAD (return) followed by RUN/STOP (for version 4.0).

MINI-EDITOR COMMANDS

Auto Line Numbering

The function of this command is to generate new line numbers for entry of source code. In order to enable the auto command type the following:

AUTO nl(return)

where nl is the increment between line numbers printed. To disable the auto function type the auto command without an increment.

Break Command

The BREAK command jumps to the ROM resident monitor. This command is executed by typing:

BREAK(return)

Change String

The change command allows the user to automatically locate and replace one string with another (multiple occurrences). This command is entered in the following format:

```
CHANGE/str1/str2/,nl-n2
```

/	Delimits the str1 and str2 (any character not in either str)
str1	Search string
str2	Replacement string
,nl-n2	Range parameters. The format is the same as the BASIC LIST command. If omitted the whole file is searched.

COLD

Resets the PET to its power on conditions. The disk unit is not reset nor is PET memory between \$0100 and \$0400. Its purpose is to clear memory to allow the HI-LOADER (MID-LOADER) to be loaded.

Delete

A delete range function has been included to make deletion quicker. The format is the same as the BASIC list command:

DELETE n1-n2

Ensure that you use the range parameters, as leaving them out causes the entire file to be deleted.

Find String

The find string command is used to locate specific strings in text. Each occurrence of the string is printed on the CRT. You can halt the printing with the SPACE bar. Printing can then be continued with the SPACE bar or terminated with the STOP key. The format of the FIND command is:

FIND/str1/,n1-n2

/	Delimiter
str1	Search string
,n1-n2	Range parm. same as BASIC list command

Formatted Print

The format command is used to print the text file in tabbed format like the assembler. For this function to work correctly you must type mnemonics in column two, or one space from labels.

FORMAT n1-n2
 n1-n2 Range parms of the same
 format as LIST.

NOTE: This command has the same controls as find. For example, SPACE halts printing, SPACE restarts, and STOP quit.

GET Files

Input assembler text files from disk. This command is used to load source files into the editor and append to files already in memory.

GET "FILE-NAME",n1,n2,n3
 n1 Begins inputting source
 at this line.
 n2 Device #, default is 8
 n3 Secondary address
 default is 8

NOTE: GET starts numbering at 1000 by 10.

KILL Command

This command causes the editor to disengage. This does not disable the repeat function if it has been turned on prior to KILL. To restart the editor, type the same command used to start the editor.

Resequenece Lines

The NUMBER function allows the user to renumber all or part of the file in memory.

```
NUMBER n1,n2,n3
      n1      Old start line number
      n2      New start line number
      n3      Step size for resequence
```

PUT Command

The PUT command outputs source files to the floppy for later assembly. PUT has the ability to output all or part of the memory resident file.

```
PUT "0:NAME",n1-n2,n3,n4
      0:      Drive number, for disk only
      NAME    Output file name
      n1      Starting line number
      n2      Ending line number
      n3      Device #, default is 8
      n4      default is 8
```

If n1-n2,n3,n4 are left out, the whole file is outputted to the default device.

When using the device number parameter to PUT a file the syntax should should be altered to

```
PUT"0:NAME",n1-,n3,n4
```

This is because of the way in which the editor parses the commands.

MINI-EDITOR COMMAND SUMMARYCOMMANDDESCRIPTION

AUTO n1	Starts automatic line numbering
AUTO	Shuts off auto
BREAK	Jump to the monitor
CHANGE/s1/s2/,n1-n2	Change string
CHANGE/s1/s2/	Change string no range
COLD	Reset the PET
DELETE n1-n2	Delete range
FIND/s1/,n1-n2	Find string
FIND/s1/	Find string no range
FORMAT n1-n2	Print formatted
GET"FILE",n1-n2,n3	Bring in text
GET"FILE"	Short form get
KILL	Disable the editor
LIST	List lines of text
NUMBER n1,n2,n3	Renumber text
PUT"0:FILE",n1-n2,n3,n4	Save text on disk
PUT"1:FILE"	Save text short form

OPERATION OF THE PET ASSEMBLER

The assembler loads as a BASIC program. To start the assembler, enter a RUN command. This works because the program starts with a SYS command which is set up in the assembler source. An example of how to start a program in this manner is given just before the appendices of this manual. When the assembler is run it will print a copyright notice and print the first user prompt.

The first user prompt is for an object filename. If no object file is desired, type a return for this prompt. If an object file is desired the response would be something like:

OBJECT FILE? 1:TESTOBJ

Note that a drive number must be specified before the filename.

The second prompt is for hard copy. A null response will produce output. You must type N for no, followed by a return to defeat the printed listing.

The hard copy may be directed to the IEEE port (device #4) or to the User Port. (User Port handshake is Centronics parallel; see the notes at the end of this appendix for details). The user determines which method by responding Y or N to the IEEE Printer question. A null response defaults to a yes.

The final prompt is for the source filename. When the user types the name of the file to be assembled followed by return, the assembler starts operation. If a null response is detected the assembler returns control to BASIC. This allows the user to correct mistakes.

Upon startup the assembler initializes both of the disk drives, opens the source file and starts the assembly. If an object file has been requested it is also opened.

There are several errors which may occur on a system level rather than an assembly level. These errors are caused by disk problems and user errors. They are generally easy to solve as is presented in the following examples.

The first is 'FILE NOT FOUND'; which is produced when one of the following occurs:

1. The source file was not found.
2. A .LIB specifies a nonexistant file.
3. A .FIL specifies a nonexistant file.

This error is of the human type: eg, the user has mistyped a filename or placed the wrong diskette into the floppy.

The second error is 'FILE EXISTS'. This error is produced when the object file named already exists on the drive specified. This error can be cured by scratching the old file or changing the diskette.

The third error is 'READ ERROR'. This error is a disk read

error. Please refer to the Disk user manual for a description of the errors and their causes.

Notes on Operation

When the assembler is running, operation may be halted by pressing the RUN/STOP key. This only halts the assembly process; operation may be terminated at this point by pressing B or T key. These keys return control to BASIC or TIM respectively. Pressing any other key continues the assembly process. This feature is useful for users without printers, as the screen listing can be examined during assembly.

The assembler can send the printed output to the User Port with a Centronics parallel handshake method. This allows the user to attach a printer other than a Commodore printer. The data is transferred byte parallel with two handshake lines, Data Strobe and Acknowledge (both active low). The data is placed on the port then the Data Strobe is pulled low 6 usecs later, starting the handshake sequence. The computer now waits for the acknowledge line to be pulled low by the printer. When this happens, the data strobe line is released and the handshake sequence is completed for one character. The following presents the interconnection for the interface. The user should keep cable lengths to a minimum, as there are no line drivers in the computer on the output lines. The user should also check the loading of the device that is being connected because the computer can only drive one standard TTL load.

Interconnection Table

<u>PET</u>		<u>Description</u>	<u>Centronics</u>
M	(cb2)	Data Strobe	1
C	(pa0)	Data 1	2
D	(pa1)	Data 2	3
E	(pa2)	Data 3	4
F	(pa3)	Data 4	5
H	(pa4)	Data 5	6
J	(pa5)	Data 6	7
K	(pa6)	Data 7	8
L	(pa7)	Data 8	9
B	(cal)	Acknowledge	10
N	(gnd)	Ground	16
A	(gnd)	Ground	33

PET LOADERS

The PET Assembler produces portable output in an ASCII format that is not directly executable. This output must be LOADED so the program can be executed. This is the function of a Loader.

There are three versions of the Loader included on the development disk. Each version is positioned in a different area of RAM memory. This allows the user to load anywhere in RAM by using the correct loader. The following table shows the names, load points and run commands for each of the three loaders.

NAME	LOAD ADDRESS	RUN COMMAND
LOADER	\$0400	RUN
MID-LOADER	\$3000	SYS 3 *4096
HI-LOADER	\$7000	SYS 7 *4096

The loaders are about 512 bytes long and all operate in the same manner. When activated, the loaders print a copyright notice and prompt the user for a load offset. The offset is used to place object code into an address range other than the one that it was assembled into. This allows the user to assemble for an area where there is no RAM and load into a RAM area. The object can then be programmed into EPROM etc..

The offset is a two byte hexadecimal address that is added to the program addresses. If the program address, plus the offset, is greater than \$FFFF, the address wraps around through \$0000. If no offset is required pressing the RETURN key defaults to a zero offset. The following examples show how offset works.

Address	Offset	Load Point
\$0400	\$0000	\$0400
\$3000	\$0000	\$3000
\$9000	\$D000	\$2000
\$E000	\$4000	\$2000

After the offset is entered, the loader will prompt the user for the object filename to be loaded. The loader will then initialize both drives, search for the file and start the load. As the data is loaded, the program will print the input data to the CRT. This is for user feedback only. When the load is completed the loader prints the message 'END OF LOAD' and returns to BASIC.

There are three errors that can happen during a load. Errors are considered fatal; the load is terminated, the object file is closed, and control is returned to BASIC if an error is encountered. The following is a list of possible errors, which should be self documenting.

BAD RECORD COUNT
NON-RAM LOAD
CHECKSUM ERROR

CAUTION: The HI-LOADER (MID-LOADER for 16K machines) and the MINI-EDITOR load into the same RAM area. You must cold start the computer before using these loaders!

EXTRAMON COMMANDS

SIMPLE ASSEMBLER

```
.A 2000 A9 12    LDA #$12
.A 2002 9D 00 80 STA $8000,X
.A 2005 DEX:GARBAGE
```

In the above example the user started assembly at 2000 hex. The first instruction was load a register with immediate 12 hex. In the second line the user did not need to type the 'A' and address. The simple assembler retyped the last entered line and prompts with the next address. To exit the assembler, type 'RETURN' after the address prompt. Syntax is the same as the disassembler output. A ':' can be used to terminate a line.

BREAK SET

```
.B 1000 00FF
```

The example sets a break at 1000 hex on the FF hex occurrence of the instruction at 1000. Break set is used with the quick trace command (see later). A break set with count blank stops at the first occurrence of the break address.

DISASSEMBLER

```
.D 2000
., 2000 A9 12    LDA #$12
., 2002 9D 00 80 STA $8000,X
., 2005 AA      TAX
```

Disassembles to the end of memory starting at 2000 hex. The three bytes following the address may be modified by using the cursor keys to move and modify the bytes. Then hit 'RETURN' and the bytes in memory will be changed. Extramon will then disassemble that line again.

```
.D 2000 3000
```

This disassembles from 2000 to 3000

ENABLE STOP

```
.E
```

This allows an exit from machine programs. If keyboard interrupts are still operating the program may be stopped by pressing the STOP and '=' keys at the same time.

FILL MEMORY

```
.F 1000 1100 FF
```

This fills the memory from 1000 hex to 1100 hex with the byte FF hex.

GO RUN.

.G

Go to the address in the PC register display and begin running code. All the registers will be replaced with the displayed values.

.G 1000

Go to address 1000 hex and begin running code.

HUNT MEMORY

.H C000 D000 'READ

This hunts through memory from C000 hex to D000 hex for the ascii string 'READ' and prints the address where it is found. A maximum of 32 characters may be used.

.H C000 D000 20 D2 FF

Hunt memory from C000 hex to D000 hex for the sequence of bytes 20 D2 FF and print the address where it is found. A maximum of 32 bytes may be used. Hunt can be stopped with the STOP key.

INTEGRATE MEMORY

.I F000

. ' F000 54 4F 4F 20 4D 41 4E 59 TOO MANY

. ' F008 20 46 49 4C 45 D3 46 49 FILESFI

This displays hex and ascii until the end of memory.

.I F000 F080

This displays hex and ascii from F000 hex to F080 hex.

LOAD FROM TAPE

.L

Load any program from tape #1

.L "RAM TEST"

Load from tape #1 the program named "RAM TEST"

.L "RAM TEST",02

Load from tape #2 the program named "RAM TEST". Beware that load with a file name breaks the IRQ saved by the monitor. Do not use the GO command after load. Exit to Basic and re-enter the monitor.

MEMORY DISPLAY

```
.M 0000 0080
.: 0000 00 01 02 03 04 05 06 07
.
.: 0080 08 09 0A 0B 0C 0D 0E 0F
```

This displays memory from 0000 hex to 0080 hex. The bytes following the address may be modified by editing and then typing a return.

NEW LOCATER

```
.N 7000 77FF 1000 0400 8000
.N 7000 77FF 1000 0400 8000 W
```

This relocates machine code from 7000 hex to 77FF hex to a new location at 1000 hex. New locator fixes all 3 byte instructions in the range 0400 hex to 8000 hex. The 'W' option will relocate .WORD tables only. The new locator will not move instructions of 00, so transfer the tables first, then zero tables in from the copy. New locator stops and disassembles on a bad OP code.

QUICK TRACE

```
.Q
.Q 1000
```

The first example begins trace at the address in the PC of the register display. The second begins at 1000 hex. Each instruction is executed as in the walk command, but no disassembly is shown. The break address is checked for break on the n'th occurrence. The execution may be stopped by pressing the STOP and '=' keys at the same time.

REGISTER DISPLAY

```
.R
      PC SR AC XR YR SP
.: 0000 01 02 03 04 05
```

This displays the register values saved when extramon was entered. The values may be changed with the edit followed by RETURN. Use this instruction to set up the PC value before single stepping with '.W'.

SAVE TO TAPE

```
.S "PROGRAM NAME",01,0800,0C80
```

Save to tape #1 from 0800 hex up to but not including 0C80 hex and call the program "PROGRAM NAME". Beware that save with a file name breaks the IRQ saved by the monitor. Do not use the GO command after save. Exit to Basic and re-enter extramon.

TRANSFER MEMORY

.T 1000 1100 5000

This transfers memory in the range 1000 hex to 1100 hex, and start storing it at address 5000 hex.

UNDO STOP KEYS

.U

This disables exit from machine language programs with the STOP and '=' keys.

WALK CODE

.W

Single step starting at address in register PC.

.W 1000

Single step starting at address 1000 hex. Walk will cause a single step to execute, and will disassemble the next instruction. You can control the speed with the following keys :-

'<' for single step
'RVS' for slow step
'SPACE' for fast stepping.

EXIT TO BASIC

.X

This returns to Basic ready mode. The stack value saved when entered will be restored. Care should be taken that this value is the same as when the monitor was entered. A 'CLR' in Basic will fix any stack problems.

MONITOR INSTRUCTIONS

G - Go run
L - Load from tape
M - Memory display
R - Register display
S - Save to tape
X - Exit to Basic

EXTRAMON INSTRUCTIONS

A - Simple assembler
B - Break set
D - Disassembler
E - Enable stop keys
F - Fill memory
H - Hunt memory
I - Integrate memory
N - New locator
Q - Quick trace
T - Transfer memory
U - Undo stop keys
W - Walk code

DEVELOPMENT AIDS

DOS Wedge	(DOS 5.1)
PET Emulator	(CBM64 TO PET)
Sound Editor	(SIDMON)
Sprite Editor	(SPED)
Character Editor	(CHRED)

PET EMULATOR

(CBM64 TO PET)

The program "CBM64 TO PET" is a short form emulator that relocates the screen and BASIC to the following locations:

Bottom of BASIC	\$0400
Top of BASIC	\$8000
Screen	\$8000

Note: The STOP/RESTORE function will NOT bring the CBM64 back to its original state after this program is run.

PREFACE

The Commodore PET EMULATOR software package allows you to execute programs that were originally designed for the Commodore PET computer on the new Commodore 64.

The PET EMULATOR modifies the CBM Model 64 so that it will operate identically to the 2.0 Basic PET 2001 in most respects. This modification consists of two parts: memory re-configuration and system interaction interpretation. The exact technical specifications of just how the PET EMULATOR operates are well outside the scope of this document, however the more important conceptual information of its operation are presented.

It is recommended that you read the entire document before trying to use the EMULATOR to ensure that your first experience will be a successful one.

USER CONVENTIONS

It is recommended that you familiarize yourself with the Commodore keyboard. Here is a brief description of certain keys and symbols, and their respective function in reference to the PET EMULATOR and this manual.

Up Arrow

The Up Arrow character, on the upper left corner of the keyboard, is used to load and execute program.

/ and %

These two keys are used to load a program into the computer's memory. A more definitive explanation will be presented later in this manual.

@ and Greater Than

These two keys are used interchangeably as the command prompt for the emulator.

2.0 Theory of Operation	1
3.0 Operation	2
4.0 DOS 5.1	2
4.1 Command Summary	3
5.0 Combinations of Mode/Memory	4

1.0 Getting Started

The operation of the PET Emulator is not only simple but really transparent to the user. It was designed by Commodore for one reason only: Software Compatability. It is our desire that you find the program useful and of real benefit. Please take a moment to make sure that you have the following equipment connected properly, as per the instructions in the Commodore 64 User Manual.

1. Commodore 64
2. Commodore 1541 Disk Drive

1.1 Loading the PET Emulator

On the diskette contained in the package there is a small program that will load and execute the PET Emulator, the Emulator itself, and several PET Public Domain programs for your enjoyment.

To load the PET Emulator type: `LOAD**",8.` After the computer replies `READY`, type `RUN`. This will load and execute the Emulator. You will notice a message appears on the screen indicating that the Emulator is loaded and running.

2.0 Theory of Operation

Memory Configuration

The CBM 64, in normal operation, stores BASIC programs in the \$0800 to \$9fff memory range (HEX), with the screen stored at \$0400 to \$0800. The PET stores BASIC programs at \$0400 to \$7fff, with the screen stored at \$8000 to \$8fff.

The Emulator re-configures the Commodore 64 memory so that it duplicates the PET internally. Thus `POKES` to the screen, `POKES` to the program, and other such direct access operations work properly.

System Interaction Interpretation

Many PET programs access the system directly with `PEEKs`, `POKEs` and `WAITs`. Most of the common `PEEKs`, `POKEs` and `WAITs` are interpreted by the Emulator and should operate exactly as they would on the PET. These locations are as follows:

Location	PEEK	POKE	Operation
50003	x		BASIC version type test
59464	x	x	CB2 sound frequency
59467	x	x	CB2 sound on/off
59466	set to 15		
59468	x	x	Set upper/lower case

All POKES and PEEKS between \$0000 and \$03ff (when possible) are translated. POKES not able to be interpreted return the message 'illegal quantity error'.

Cassette buffer #2 is also available for machine code programs (same as the PET). Machine language programs that do not call system routines will work with no modifications if they reside in this cassette buffer.

The CB2 sound is emulated as closely as possible. Certain very high tones available on the PET can not be obtained on the 64, and the pitch of the tones varies across the scale. Musical tunes may not be emulated correctly, but other sound effects usually sound better under the emulator than they may have on the PET.

3.0 Operation

The Emulator loads into high memory on the 64, \$C000 (HEX). It may be loaded directly by typing: `LOAD"EMULATOR",8,1` and then after the computer replies READY, type `SYS 12*4096`. As stated above, the first program on the diskette is a program that will load and execute the Emulator for you. In addition this program contains the logic to allow screen color selections before actually loading the Emulator.

4.0 DOS 5.1

Included on the diskette, and operable with the Emulator, is another valuable product from Commodore, the DOS 5.1 Universal Disk Operating System program. This program is more commonly called the DOS Wedge because it 'wedges' itself in between the computer and the disk drive to facilitate disk operations such as LOAD and SAVE.

The DOS Wedge provides a very useful 'short cut' method of communicating with the disk drive. It cannot make the disk drive do anything more than can be done through commands in a BASIC program, but allows the user to communicate in a direct mode.

This version of the DOS Wedge will actually allow the 'short form' commands to be given from within a BASIC program as well.

4.1 Command Summary

Normal DOS Wedge Commands

up arrow	Load and Run a program
/	Load a program into the normal BASIC program area
%	Load a program into the area in memory dictated by the programs load address
left arrow	Save a program
@	Read and display the disk drive error channel
@\$x	Display the directory of the disk in drive x (ie. @\$0 for drive 0)
@\$x:pgm*	Search the directory on drive x for the files that begin with 'pgm'
@n:name,id	Header a NEW disk, using 'name' and 'id'
@r0:a=b	Rename file 'b' on drive 0 to 'a'
@c0:a=0:b	Copy file 'b' on drive 0 to file 'a' on drive 0
@s0:name	Scratch file 'name' on drive 0
@uj.	Reset disk drive
@#9	Change the active unit number from the default value of 8 to 9
@q	Quit, turn off, the DOS Wedge and the Emulator
@ix	Initialize disk drive x

File names for the LOAD and SAVE commands may be within quotes anywhere on a line of the screen (as in a directory listing), and all other extraneous information on the line is ignored.

Using the DOS Wedge from within a program:

```
10 INPUT "DO YOU WANT TO LIST THE DISK DIRECTORY";A$
20 IF A$="Y" GOTO 40
30 STOP
40 @$0"
```

5.0 Combinations of Mode/Memory

New commands added to the DOS Wedge to support the Emulator include:

- @m toggle memory configuration
- @e toggle emulate mode (PET/64)

Either of the latter two commands will display the current mode/memory status. The @m command 'news', erases, the BASIC program currently in memory. Therefore, 'are you sure' is asked before the command is executed.

The emulator normally loads up into the PET memory mode with the PET emulator on. Thus four combinations of mode/memory exist. When changing modes warnings are printed where potential confusion exists. Now once the computer is in PET memory mode with the Emulator on, the system operates as a PET as described above. When in 64 memory mode with the emulator off, the emulator has no effect on the normal operation of the Commodore 64.

Please note that when in the PET memory mode the RUN/STOP key is disabled.

SOUND EDITOR

(SIDMON)

SIDMON allows you to create sounds by editing the SID chip registers. (A detailed description of the SID chip can be found in Section II of this binder.) To load SIDMON enter:

LOAD "SIDMON",8
RUN

The following screen will appear:

```

MODE:                                *** SIDMON 1.3 ***

[FREQUENCY]                          [PULSE WIDTH]
5000                                1024
5000                                2048
5000                                3072
                                     (for voice 1)
                                     ( " 2)
                                     ( " 3)

[CUTOFF] FREQUENCY: 0

VOICE: ([F1],[F3],[F5]): 1
    
```

[+/-] UP/DN/ON/OFF

[D] DIVIDE BY TWO

[M] MULTIPLY BY TWO

Commands are entered by pressing the reversed key (□) associated with that function. Up/down and on/off settings are controlled by pressing the "+" and "-" keys. This is best described by using examples:

First select your wave form (^ / □ *) by pressing 1,2,3 or 4.
Then, gate the sound ON by pressing "G" followed by "+".
Next you can alter the frequency by pressing "F", followed by:

- + to raise the frequency
- to lower the frequency
- M to multiply the frequency by 2
- D to divide the frequency by 2

Attack, decay, sustain, release, etc. can be altered in the same manner. Any one of the three voices can be selected by F1, F3, or F5.

After creating the desired sound, jot down the numbers in the registers for later use in your programs.

SSSS	IIIIII	DDDDD	MMM	MMM	OOO	NNN	NN
SS SS	II	DD DD	MMMM	MMMM	OO OO	NNNN	NN
SS	II	DD DD	MM MM	MM MM	OO OO	NN	NNNN
SSSS	II	DD DD	MM	MMMM	MM	OO OO	NN NNN
SS	II	DD DD	MM	MM	MM	OO OO	NN NN
SS SS	II	DD DD	MM		MM	OO OO	NN NN
SSSS	IIIIII	DDDDD	MM	MM	OOO	NN	NN

Sound Interface Device MONitor

SIDMON

SIDMON is a program which allows you to create sounds using the 6581 Sound Interface Device in the Commodore 64. It is difficult to randomly try different sounds or keep poking around until you get the sound you want. SIDMON does all of the poking for you. You just look at the screen and change whatever you want. If you don't like the change, change it back. It's that simple to use!

The commands are usually the first letter of the register name. In some cases though, the letter has already been taken by another command, so the second letter is used instead. The proper letter to press is highlighted in reverse on the screen.

First, lets review the descriptions of the different registers...

FREQUENCY : This register sets the number of sound waves per second produced by the SID.

PULSE WIDTH : This register forms a number which linearly controls the duty cycle of the pulse waveform on the voice that is being worked on.

ATTACK : The attack rate determines how rapidly the output of the voice rises from zero to peak amplitude when the voice is gated.

DECAY : The decay cycle follows the attack cycle and the decay rate determines how rapidly the output falls from peak amplitude to the selected sustain level.

SUSTAIN : You can select 1 of 16 sustain levels for the voice. The sustain cycle follows the decay cycle and the voice will remain at the selected sustain level as long as the gate bit remains on (1).

RELEASE : There are 0 to 15 release levels of which one can be selected. The release cycle follows the sustain cycle when the gate bit is turned off (reset to zero). At this time, the output of the voice being worked on will fall from the sustain amplitude to zero amplitude at the selected release rate.

GATE : When the gate is set to a one, the attack/decay/sustain cycle begins. When the gate is reset to a zero, the release cycle begins. The gate must be set for the selected output of the voice to be audible.

SYNC : The sync, when set to a one, synchronizes the fundamental frequency of the voice being worked on with the frequency of voice 3. Varying the frequency of the present voice with respect to voice 3

produces a wide range of harmonic structures from the present voice at the frequency of voice 3. In order for sync to occur, voice 3 must be set to some frequency other than zero but preferably lower than the frequency of the present voice. No other parameters of voice 3 have any effect on sync.

RING : The ring register, when set to a one, replaces the triangle waveform of the present voice with a ring modulated combination of the present voice and voice 3. Varying the frequency of the present voice with respect to voice 3 produces a bell or gong-like sound.

△: The triangle waveform has a mellow, flute-like quality.

∇: The sawtooth waveform is rich in even and odd harmonics and has a bright, brassy quality.

□: The harmonic content of the pulse waveform can be adjusted by the pulse width register, producing tone qualities from a bright, hollow square wave to a nasal, reedy pulse.

* : This output is a random signal. The sound quality can be varied from a low rumbling to a hissing white noise via the frequency register.

FILTER : When set to a zero, the present voice appears directly at the audio output and the filter has no effect on the sound. If set to a one, the present voice will be processed through the filter and the harmonic content of the voice will be altered.

RESONANCE : This register controls the resonance of the filter.

Resonance is a peaking effect which emphasizes frequency components at the cutoff frequency of the filter, causing a sharper sound. There are 16 resonance settings ranging linearly from no resonance (0) to maximum resonance (15).

LOW : When set to a one, the low pass output of the filter is selected and sent to the audio output. For a given filter input signal, all frequency components above the cutoff are attenuated at a rate of 12 dB/octave. The low pass mode produces full bodied sounds.

BAND : This is similar to LOW but, all frequency components above and below the cutoff are attenuated at a rate of 6 dB/octave. The band pass mode produces thin, open sound.

HIGH : This is the opposite of LOW, in that when set to a one, all frequency components below the cutoff are attenuated at a rate of 12dB/octave. This mode produces a tinny, buzzy sound.

CUT 3 : When set to a one, the output of voice 3 is disconnected from the direct audio path. Setting voice 3 to bypass the filter and setting cutoff 3 to a one prevents voice 3 from reaching the audio output. This allows voice 3 to be used for modulation purposes without any undesirable output.

MASTER VOLUME : Select one of 16 overall volume levels for the final composite audio output. The values this register can hold range from 0

(no sound) to 15 (max sound).

CUTOFF FREQUENCY : This register is set to contain a number which controls the cutoff (or center) frequency of the programmable filter.

SIDMON COMMANDS :

There are several commands that are used in SIDMON. These commands, as mentioned before, are highlighted on the screen in reverse. When a valid key is pressed, that key is displayed next to "MODE:" on the top line. The only keys that will not be displayed are +, -, M and D. For these keys to have any effect, another letter must already be displayed next to the mode.

CLR HOME : To completely reset SIDMON press the <SHIFT> and <CLR HOME>. All of the values will be reset to their default. NOTE: ANY CHANGES YOU HAVE MADE WILL BE LOST!!!

F1, F3 and F5 : These three function keys are used to select the voice that you are currently working on. F1 is voice 1. F3 is voice 2 and F5 is voice 3. The voice that is presently being worked on is noted next to where it says "VOICE (F1,F3,F5):" on the bottom line of the screen.

+/- : The add and subtract keys are used to raise or lower values in the different registers. In some cases, such as "gate" which is either off or on, the plus (+) key is used to turn on and the minus (-) key is

used to turn off.

M/D : The "M" key and the "D" keys are used to multiply or divide respectively. These keys work only on frequency and on pulse width.

F : The "F" key is used to select frequency. Follow this key with either +, -, M or D to change the frequency. While in frequency mode, the plus and minus keys add or subtract 16 from the frequency of the voice that you are working on. If you only want to add 8 to the frequency, multiply the frequency by two by using the "M" key. Then, using the "+" key add 16, then divide by 2. Your frequency should now be 8 more than when you started.

P : To select pulse width, press the "P" key. The pulse width mode is similar to the frequency mode. The only difference is that the plus and minus keys change the pulse width by 64. Remember, pulse width only applies when you are using square wave.

A, D, S and R : These keys select attack, decay, sustain and release, respectively. The values of each range from 0 to 15. Plus and minus change these registers by 1. The "M" and "D" keys do not work while in this mode.

G : This key selects gate. A one (+) in this register starts the attack, decay and sustain. When reset to a zero (-), the release sequence begins. This register must be manipulated for you to get any sound from the SID.

Y and I : These keys select sync and ring. On and off are the only 2 states these registers can have. The + key turns the register on and the - key turns it off.

0, 1, 2, 3 and 4 : Keys one thru four select the type of waveform that the voice you are working on will have. The "1" key selects triangle. "2" selects sawtooth. Pulse is chosen by pressing the "3" key and the "4" key selects noise. For pulse width to have any effect, the pulse waveform must be selected. Only one of these four choices may be on at any one time. The 0 key will turn off all waveforms.

T : This selects filter. As in gate, sync and ring, the filter has either an on or an off state.

E : Resonance can be set by pressing the "E" key. It has a range of 0 to 15, which can be modified by using the + and - keys.

V : SIDMON has a master volume which can be changed by pressing "V" followed by + or - keys.

U : The cutoff frequency is selected by pressing "U". This, followed by + or -, changes the cutoff frequency. (Divide and multiply does not work in this mode.)

Try to recreate this sample:

MODE: *** SIDMON 1.4 ***

For more information on the SID, see the Programmers' Reference Guide.

CHARACTER EDITOR

The characters that are printed onto the screen through PRINT statements (or POKE statements to screen memory) are stored in ROM. There are two such character sets, each occupying 2K (2048) bytes.

- 1) The usual GRAPHICS character set (POKE 53272,21)
- 2) The LOWER CASE character set (POKE 53272,23)

On the COMMODORE 64, it is possible to have character sets stored in RAM - 8 are theoretically possible - 5 are actually usable.

The RAM character sets are numbered 0-7. Each set occupies 2K of memory and is activated by poking register 24 of the 6566 Video Chip (i.e. memory location 53272) with an appropriate number.

CHARACTER SET	LOCATION	ENABLE WITH
0	0 - 2047	POKE 53272,17
1	2048 - 4095	POKE 53272,19
2	4096 - 6143	POKE 53272,21
3	6144 - 8191	POKE 53272,23
4	8192 - 10239	POKE 53272,25
5	10240 - 12287	POKE 53272,27
6	12288 - 14335	POKE 53272,29
7	14336 - 16383	POKE 53272,31

Notes:

- 1) Character Set 0 is not available since this part of memory is used by the operating system and screen memory.
- 2) The Pokes that enable Character Sets 2 and 3, in fact, enable the ROM character sets.

Thus the only character sets that are available for use in RAM are sets 1, 4, 5, 6, and 7. Since these sets are located in the same part of memory that a BASIC program normally occupies, it may be necessary to move the BASIC program up in memory whenever a RAM character set is used (See the instructions in the GSprite Editor to see how this is done). This will not always be necessary. For example, if an application program only requires 6-8K of memory, then Character Sets 5, 6, or 7 could be used, and could even be saved with the BASIC program itself - thus avoiding having to load the character set from within the program.

This CHARACTER EDITOR allows you to create, edit, etc. any of the five available character sets. Any set you create can be saved to disk to be used within your programs.

There are two distinct modes in this editor, each with its own set of commands - CHARACTER SELECTION MODE and EDIT MODE.

CHARACTER SELECTIONS MODE

This is the mode that the Character Editor starts with when it is first run. In this mode, a box cursor flashes over one of the 64 characters displayed near the bottom of the screen (whenever this box cursor flashes, you know that you are in CHARACTER SELECTION MODE and not in EDIT MODE).

The cursor can be moved from character to character using the normal cursor keys (up, down, left, and right). When the cursor is positioned over the character you wish to edit, press the RETURN key. That character will then be displayed on the EDIT GRID at the upper left of the screen ready for editing. The character will also be displayed to the right of the edit grid in each of the 16 colors.

While in Character Selection Mode, several commands are available. These are summarized in the following table.

Keystroke	Effect
CRSR-RT, LFT, -UP, DOWN	Moves the box cursor to any of the 64 characters displayed on the screen.
RETURN	Selects the character under the cursor for editing. The character is displayed on the EDIT GRID and EDIT MODE is entered.
CTRL-N	Displays the NEXT 64 characters of the present character set at the bottom of the screen (There are 256 characters in each character set, but only 64 are displayed at any given time).
CTRL-2	Steps through each of the 16 BACKGROUND colors.
CTRL-3	Steps through each of the 16 EDGE (Border) colors.
Any of the # keys 1-7.	Displays the corresponding character set. (Note: Character Sets 2 and 3 can be displayed but since they are in ROM they cannot be edited.)
CTRL-L	LOADS a specified character set from disk into memory.
S	SAVES the character set, presently being edited, to disk. You are prompted for a filename and the number of the set you wish to save that set to. (Note: If you are presently editing Character Set 1, say, you can still save it to Character Set 4, 5, 6, or 7 if you wish.)
Q	QUIT the editor. Once you have quit the editor, you may restart it, with all character sets intact, simply by typing RUN. The CHRR BOOT Program does not have to be reloaded and run.

EDIT MODE

The commands available in Edit Mode are almost exactly the same as the commands available to the Sprite Editor.

The following commands are exactly the same (See the Sprite Editor's Instructions).

- a) CRSR-RT, CRSR-LFT, CRSR-UP, CRSR-DWN.
- b) SPACE, DEL, ., HOME, RETURN, CLR.
- c) CTRL-R, F1, F2, F3, F4, &.
- d) CTRL-B, CTRL-E.

The following commands are not implemented, simply because they do not apply to character sets.

- a) CTRL-P, +, -, CTRL-D, CTRL-C.
- b) >, CTRL-W, CTRL-Y, CTRL-V.

Note: B and CTRL-L are not implemented in Edit Mode, but are available in Character Selection Mode.

ADDITIONAL COMMANDS

- a) CTRL-R : This allows the character being edited to be ASSIGNED to some character in the character set. When CTRL-R is pressed, the box cursor flashes over the character originally selected. The edited character can be assigned to this character or to another character by first using the cursor keys and/or CTRL-N to position the cursor over the desired character and then pressing RETURN.
- b) B : Pressing B in Edit Mode allows you to re-enter Character Selection Mode without assigning the character to any character in the character set. The edited character, however, is lost.

NOTE: To use the Character Editor, the program CHRR EDIT must be loaded and run first.

SPRITE EDITOR

The data that defines a sprite on the Commodore 64 is stored in 64 consecutive bytes called a 'Page' (this is not the usual Page concept associated with the 6502 or 6510). Up to 256 sprite definitions are theoretically possible, but not all of these are available.

The sprite Pages start at the beginning of memory, so for example, Page 0 occupies memory locations 0-63, Page 1 occupies locations 64-127, and so on. Page 32 begins at $32 \times 64 = 2048$ and extends for 64 bytes, page 150 begins at $150 \times 64 = 9600$, and so on.

Since the operating system uses most of the memory locations from 0-2048 for its own use, several Pages here will not be available for sprite definitions. Others are not available as well.

Here is what is available and what is not.

Sprite Pages	Memory Locations	Status	Reason
0-12	0-831	Not Available	Operating system
13-15	832-1023	Available	Cassette buffer
16-31	1024-2047	Not Available	Screen Memory
32-63	2048-4095 (2K)	Available	See below
64-127	4096-8191 (4K)	Not Available	I don't know why!!
128-255	8192-16383 (8K)	Available	See below

Normally Pages 32-63 (and some in the range 128-255) would not be available for sprite definitions since the BASIC Program is stored there. However, it is easy to move a BASIC Program UP in memory to wherever you wish. Thus this area can be considered as available for use.

For example, to move a BASIC program UP so that it starts at 16384, and hence make available ALL of the room above, the following steps are required:

- 1) POKE 16#1024,0 (Note: $16 \times 1024 = 16384$)
- 2) POKE 44,16#4
- 3) POKE 43,1 (Normally this location is 1, so this step may not be required.)
- 4) LOAD "YOUR PROGRAM" as usual.

These steps could be done in a small boot program, such as the SPRITE BOOT program, so that the user will not have to be concerned with such details.

This Sprite editor allows you to create, edit, save, etc. sprite definitions on any of these pages. A sprite is created or edited on a 24×21 grid (matrix) using the following commands:

Keystroke	Effect
CRSR-RT	Move the cursor (indicated in reverse field) one location to the right. When at the extreme right end of a line, the cursor will wrap around to the beginning of the same line.
CRSR-LFT	Move the cursor Position one location to the left. Wrap around can occur to the right of the same line.
CRSR-UP	Move the cursor one line UP. Wrap around can occur to the bottom of the same column.
CRSR-DWN	Move the cursor one line down. Wrap around can occur to the top of the same column.
SPACE	Erase any Point Plotted at the current cursor Position.
DEL	Erase any Point Plotted at the Previous cursor Position.
Note: These six commands are supported by the repeat key.	
.	Plot a Point at the current cursor Position.
HOME	Move the cursor to the top left corner of the grid.
RETURN	Move the cursor to the beginning of the next line. Wrap around can occur to the top (home) Position.
CLR	Erases all Points on the grid.
CTRL-R	Reverses the entire Grid.
F1	Move the entire Grid UP one line.
F2	Move the entire Grid down one line.
F3	Move the entire Grid left one column.
F4	Move the entire Grid right one column.
3	Rotates the sprite 90 degrees.

Note: Rotating a 24 X 21 sprite can cause part of the sprite to disappear (since it is not square). The part that disappears is in fact preserved in a buffer, as can be seen by Pressing the Pound key once again - the sprite should now be upside down. Pressing it twice in succession again will bring it back to its original position - in fact, Pressing RETURN at any time will put you back into EDIT mode. Whatever you see on the screen will be stored in the sprite definition and anything else in the buffer will be lost.

CTRL-P Prompts for a new Page number which is then displayed for editing purposes.

+ Display the sprite on the next page for editing.

- Display the sprite on the previous page for editing.

CNTL-D Display a range of sprites for viewing only.

S Save a range of sprite definitions to disk.

CTRL-L Load a previously stored table of sprites into memory.

CTRL-C Copy a range of sprite definitions from one area of memory to another.

CTRL-B Steps through each of the 16 Background colours.

CTRL-E Steps through each of the 16 Edge (Border) colours.

> Steps through each of the 16 sprite colours.

CTRL-X Expand/contract the sprite being edited in the horizontal direction (acts like a toggle).

CTRL-Y Expand/contract the sprite being edited in the vertical direction (acts like a toggle too).

CTRL-V View the sprite, currently being edited, moving randomly on a clear screen.

PRESSING

SPACE : stops the motion (Press SPACE again to restart it).

RETURN : returns you to the EDITOR.

CTRL-B, CTRL-E, CTRL-X, CTRL-Y, and > have the same effect as above.

+ : speeds up the motion.

- : slows down the motion.

Q Quits the EDITOR.
 (Once you have quit the EDITOR, you can restart it simply by typing RUN. You do not have to re-load the BOOT program.)

Note: To use the SPRITE EDITOR, you must load and run the SPRITE BOOT program first.

SPRITE EDITOR (SPED)

INTRODUCTION

This program allows you to easily create and modify sprites on the Commodore 64. Many features to allow easy manipulation of sprites are included, as well as several commands to make the sprites created by this program usable by other programs.

SCREEN FORMAT

The screen is basically divided into 4 areas by the sprite editor program. The first is the large sprite creation box. Here the sprite is formed using the "*" and " " symbols. The horizontal axis of the box is lettered from 0 to 23, giving 24 possible bit positions. The vertical axis is numbered from 0 to 20, giving 21 possible bit positions. In this box, an entire sprite is represented.

The second area is the information box. Current sprite parameters are displayed here. Also, when a command needs a parameter to operate, a cursor will appear at the appropriate place in this box.

The third area is the strip below the creation box. Here is where the sprite currently being edited normally appears.

The fourth area contains the command menu, where most of the commands are displayed. However, the menu in the area under the information box can be replaced by the current sprite by the F1 key. This is especially useful when working with expanded sprites.

General Notes: The first letter of a command is enough. When a command requires an input (like sprite number), a cursor will appear in the information box. Type the answer there, ending it with a return. If you type an incorrect letter, use the delete key. If your response is illegal, the program will ignore it, keeping the old value of the parameter.

(SPED) cont.

THE INFORMATION BOX

The information box contains the following information:

PARAMETER	POSSIBLE VALUES
1. Sprite number	0-47
2. Name of current file	any 5 letters
3. Assumed address	any 4 digit hex number
4. Range	0-47
5. Type of sprite displayed	HIRES or MULTI
6. Foreground color	any of the 16 colors
7. Multi-color register 0	any of the 16 colors
8. Multi-color register 1	any of the 16 colors
9. X expand	YES or NO
10. Y expand	YES or NO
11. X position	0-319
12. Y position	0-199
13. The bottom blank line of the information box is used for other command inputs that don't need to be continually displayed.	

COMMANDS

1. E(dit) : requests a sprite number from 0 to 47. That sprite becomes the current sprite. The current appearance of the sprite is displayed both in the creation box and the current display area.
2. N(ext sprite) : selects the next sprite as the current sprite.
3. T(ype) : selects between displaying the current sprite as a hires (h) or a multi-color (m) sprite.
4. M(ove here) : asks for a sprite number. That sprite is copied into the current sprite. Note that this operation destroys the previous sprite.
5. O(r) : asks for a sprite number. That sprite is ORed into the current sprite.
6. C(olor) : allows choice of colors for the sprites. A cursor will appear at each of the color parameters in turn. Type the three letter abbreviation for the color of your choice for each register in turn.
7. X(pand) : selects expansion in the x and y directions. A cursor will appear at the XEXP and YEXP positions on the information box. Answer YES or NO (or Y or N).
8. P(osition) : allows specification of the screen position of the current sprite.
9. R(ange) : sets a range of sprites for use with the SAVE, LOAD, BYTE, and DISPLAY commands. The form is ##.## (i.e. 0:12), for first and last sprites to be affected by an operation.
10. D(isplay) : animation command. A time is requested. Answer with a number under 1000. Just hitting return allows animation under direct keyboard control. To end the display sequence hit the return key.
11. A(ddress) : this command selects the assumed address of the sprite data. This is used when the sprites are saved. If they are reloaded by a BASIC load command, that is where they will load.
12. S(ave) : asks for a file name, then saves the current range of sprites to disk, as a program file using the assumed address.
13. L(oad) : asks for a file name, then loads the current range of sprites from disk into the work area from that program file.
14. B(yte) : asks for a file name, then saves the current range of sprites to disk, as a sequential file compatible with Commodore's Assembler Development System.
15. Q(uit) : exits the program.
16. Z : rotates the current sprite. First, the center of rotation is requested on the bottom line of the information box. X values range from 0 to 23, while Y values range from 0 to 20. Then the angle of rotation is requested. Following normal conventions, clockwise angles are positive, while counter clockwise angles are negative. Note: often a sprite is distorted by rotation.
17. F1 : toggles the selection of the current sprite display area from under the creation box to under the information box and back again.
18. F3 : step through possible screen colors.

EDITING COMMAND KEYS

These commands operate on the current sprite in the creation box.

1. * : places a dot at the current cursor position.
2. SPACE BAR : places a space (removes a dot) from the current cursor position.
3. CRSR RIGHT : moves the cursor one position to the right.
4. CRSR LEFT : moves the cursor one position to the left.
5. CRSR UP : moves the cursor one line up.
6. CRSR DOWN : moves the cursor one line down.
7. RETURN : moves the cursor to the start of the current line.
8. HOME : moves the cursor to the top left corner of the sprite.
9. CLR : erases the current sprite.
10. RVS : reverses the current sprite.
11. INST : moves all dots on the current one place to the right.
12. DEL : moves all dots on the current line one place to the left.
13. + : moves all lines from the current line to the bottom line one line down.
14. - : moves all lines from the current line to the top line, one line up.

CHARACTER EDITOR (CHRED)

INTRODUCTION

This program allows editing of single characters, or editing four characters at a time (a 16 bit by 16 bit character). When editing expanded characters, all character editor commands are adjusted to operate on the expanded character. More details on expansion can be found under the X(pand) command.

SCREEN FORMAT

The screen is basically divided into five areas by the character editor program. The first is the large character creation box. Here the character is formed by using the "*" and " " symbols. In this box, an entire character is represented.

The second area is the information box. Current character parameters are displayed here. Also, when a command needs a parameter to operate, a cursor will appear at the appropriate place in this box.

The third area is the strip below the creation box. Here is where the entire current character set is displayed. Also, the character currently being edited is highlighted in black.

The fourth area is the display area, where the current character appears.

The fifth area is the command menu, where most of the commands are displayed.

General Notes: The first letter of a command is enough. When a command requires an input (like character number), a cursor will appear in the information box. Type the answer there, ending it with a return. If you type an incorrect letter, use the delete key. If your response is illegal, the program will ignore it, keeping the old value of the parameter.

(CHRED) cont.

THE INFORMATION BOX

The information box contains the following information:

PARAMETER	POSSIBLE VALUES
1. Character number	0-63
2. Name of current file	any 5 letters
3. Assumed address	any 4 digit hex number
4. Range	0-63
5. Type of character displayed	HIRES or MULTI
6. Foreground color	any of the 16 colors
7. Multi-color register 0	any of the 16 colors
8. Multi-color register 1	any of the 16 colors
9. X expand	YES or NO
10. The bottom blank line of the information box is used for other command inputs that don't need to be continually displayed.	

(CHRED) cont.

COMMANDS

1. E(dit) : requests a character number from 0 to 63. That character becomes the current character. The current appearance of the character is displayed both in the creation box and the current display area.
2. N(ext character) : selects the next character as the current character.
3. T(ype) : selects between displaying the current character as a hires (h) or a multi-color (m) character.
4. M(ove here) : asks for a character number. That character is copied into the current character. Note that this operation destroys the current character.
5. C(olor) : allows choice of colors. A cursor will appear at each of the color parameters in turn. Type the three letter abbreviation for the color of your choice for each register in turn.
6. X(pand) : selects either 8 bit by 8 bit characters or 16 bit by 16 bit characters. Answer YES or NO (or Y or N) to select expansion. When expansion is selected, four contiguous characters will be treated as a single entity for the purpose of all commands. The creation box will be expanded. The characters are edited in the following format.

1	3
2	4
7. F(ont) : masking function from the Commodore 64 ROM. The program asks if you want to mask all the characters. Answering Y replaces the current character set with the upper case character set from ROM. If you answer N (or just hit RETURN), the program will ask for a character number (from 0 to 63). That character from ROM will be copied into the current character.
8. R(ange) : sets a range of characters for use with SAVE, LOAD, BYTE, and DISPLAY commands. The form is ##:## (i.e. 0:12), for first and last characters to be affected by an operation.
9. O(r) : like move, but doesn't erase the current character first.
10. A(ddress) : this command selects the assumed address of the character data. This is used when the characters are saved. If they are reloaded by a BASIC load command, that is where they will load.
11. S(ave) : asks for a file name, then saves the current range of characters to disk, as a program file using the assumed address.
12. L(oad) : asks for a file name, then loads the current range of characters from disk into the work area from that program file.
13. B(yte) : asks for a file name, then saves the current range of characters to disk, as a sequential file compatible with Commodore's Assembler Development System.
14. Q(uit) : exits the program.
15. V(alue) : displays the values of the bytes which make up the current character. These values appear next in the character display area. This display lasts until any key is hit. Then the normal character display reappears.
16. H(ex flag) : toggles whether the V(alue) display will be in decimal or in hex.
17. F3 : step through possible screen colors.

EDITING COMMAND KEYS

These commands operate on the current character in the creation box.

1. * : places a dot at the current cursor position.
2. SPACE BAR : places a space (removes a dot) from the current cursor position.
3. CRSR RIGHT : moves the cursor one position to the right.
4. CRSR LEFT : moves the cursor one position to the left.
5. CRSR UP : moves the cursor one line up.
6. CRSR DOWN : moves the cursor one line down.
7. RETURN : moves the cursor to the start of the current line.
8. HOME : moves the cursor to the top left corner of the character.
9. CLR : erases the current character.
10. RVS : reverses the current character.
11. INST : moves all dots on the current one place to the right.
12. DEL : moves all dots on the current line one place to the left.
13. + : moves all lines from the current line to the bottom line one line down.
14. - : moves all lines from the current line to the top line, one line up.

Notes:-

- 1) The base address in the Max System is 400 (1024)
- 2) The sprite pointer address offset is 03F8 (hex 03F8)
- 3) The base address of the Color Matrix is 0500

The image shows two hand-drawn grids on lined paper. The top grid is labeled with numbers 1-10 on the left and 1-10 on the top. The bottom grid is labeled with numbers 1-10 on the left and 1-10 on the top. Both grids are 10x10 squares.

Hand-drawn grid paper with a wavy horizontal line across the middle. The grid is divided into two sections. The top section has a vertical axis on the left labeled 0 to 6 and a horizontal axis at the top labeled 0 to 6. The bottom section has a vertical axis on the left labeled 0 to 20 and a horizontal axis at the bottom labeled 0 to 6. The grid lines are hand-drawn and slightly irregular.

USERS GUIDE FOR THE 6366/6367 VIDEO INTERFACE CHIPS

The 6366/6367 are multi-purpose color video controller devices for use in both computer video terminals and video game applications. Both devices contain 47 control registers which are accessed via a standard 8-bit microprocessor bus (63XX) and will access up to 16K of memory for display information. The various operating modes and options within each mode are described.

CHARACTER DISPLAY MODE

In the character display mode, the 6366/6367 fetches CHARACTER POINTERS from the VIDEO MATRIX area of memory and translates the pointers to character dot location addresses in the 2,048 byte CHARACTER BASE area of memory. The video matrix is comprised of 1,000 consecutive locations in memory which each contain an eight bit character pointer. The location of the video matrix within memory is defined by VM13-VM18 in register 24 (318) which are used as the 4 MSB of the video matrix address. The lower order 16 bits are provided by an internal counter (VC3-VC8) which steps through the 1000 character locations. Note that the 6366/6367 provides 14 address outputs; therefore additional system hardware may be required for complete system memory decodes.

CHARACTER POINTER ADDRESS

A13	A12	A11	A10	A09	A08	A07	A06	A05	A04	A03	A02	A01	A00
VM13	VM12	VM11	VM10	VC9	VC8	VC7	VC6	VC5	VC4	VC3	VC2	VC1	VC0

The eight bit character pointer permits up to 256 different character definitions to be available simultaneously. Each character is an 8x8 dot matrix stored in the character base as eight consecutive bytes. The location of the character base is defined by C313-C311 also in register 24 (318) which are used for the 3 most significant bits (MSB) of the character base address. The 11 lower order addresses are formed by the 3 bit character pointer from the video matrix (07-08) which selects a particular character, and a 3 bit raster counter (RC2-RC0) which selects one of the eight character bytes. The resulting characters are formatted as 25 rows of 40 characters each. In addition to the 3 bit character pointer, a 4-bit COLOR NYBBLE is associated with each video matrix location (the video matrix memory must be 12 bits wide) which defines one of sixteen colors for each character.

CHARACTER DATA ADDRESS

A13	A12	A11	A10	A09	A08	A07	A06	A05	A04	A03	A02	A01	A00

PROPRIETARY INFORMATION COMMODORE INTL

13 MAY 1982

STANDARD CHARACTER MODE

(MCM = BMM = ECM = 0)

In the standard character mode, the 8 sequential bytes from the character base are displayed directly on the 8 lines in each character region. A "0" bit causes the background #0 color (from register 33 (\$21)) to be displayed while the color selected by the color nybble (foreground) is displayed for a "1" bit (see Color Code Table).

FUNCTION	CHARACTER BIT	COLOR DISPLAYED
Background	0	Background #0 color (register 33 (\$21))
Foreground	1	Color selected by 4-bit color nybble

Therefore, each character has a unique color determined by the 4-bit color nybble (1 of 16) and all characters share the common background color.

MULTICOLOR CHARACTER MODE

(MCM = 1, BMM = ECM = 0)

Multi-color mode provides additional color flexibility allowing up to four colors within each character but with reduced resolution. The multi-color mode is selected by setting the MCM bit in register 22 (\$16) to "1", which causes the dot data stored in the character base to be interpreted in a different manner. If the MSB of the color nybble is a "0", the character will be displayed as described in standard character mode, allowing the two modes to be inter-mixed (however, only the lower order 3 colors are available). When the MSB of the color nybble is a "1" (if MCM.MSB(CM) = 1) the character bits are interpreted in the multi-color mode:

FUNCTION	CHARACTER BIT PAIR	COLOR DISPLAYED
Background	00	Background #0 Color (register 33 (\$21))
Background	01	Background #1 Color (register 34 (\$22))
Foreground	10	Background #2 Color (register 35 (\$23))
Foreground	11	Color specified by 3 LSB of color nybble

Since two bits are required to specify one dot color, the character is now displayed as a 4 x 8 matrix with each dot twice the horizontal size as in standard mode. Note, however, that each character region can now contain 4 different colors, two as foreground and two as background (see MDS priority).

000 100 200 300
000 100 200 300

FIG 1. Multi-color mode character display. The character is displayed as a 4 x 8 matrix. The background color is determined by the MSB of the color nybble. The foreground color is determined by the 3 LSB of the color nybble. The character is displayed as a 4 x 8 matrix with each dot twice the horizontal size as in standard mode.

EXTENDED COLOR MODE

(ECM = 1, BMM = MCM = 0)

The extended color mode allows the selection of individual background colors for each character region with the normal 8x8 character resolution. This mode is selected by setting the ECM bit of register 17 (\$11) to "1". The character dot data is displayed as in the standard mode (foreground color determined by the color nybble is displayed for a "1" data bit), but the 2 MSB of the character pointer are used to select the background color for each character region as follows:

CHAR POINTER MS BIT PAIR	BACKGROUND COLOR DISPLAYED FOR 8-BIT
00	Background #0 color (register 33 (\$21))
01	Background #1 color (register 34 (\$22))
10	Background #2 color (register 35 (\$23))
11	Background #3 color (register 36 (\$24))

Since the two MSB of the character pointers are used for color information, only 64 different character definitions are available. The 6366/6367 will force C310 and C39 to "0" regardless of the original pointer values, so that only the first 64 character definitions will be accessed. With extended color mode each character has one of sixteen individually defined foreground colors and one of the four available background colors.

NOTE - Extended color mode and multi-color mode should not be enabled simultaneously.

BIT MAP MODE

In bit map mode, the 6366/6367 fetches data from memory in a different fashion, so that a one-to-one correspondence exists between each displayed dot and a memory bit. The bit map mode provides a screen resolution of 320H x 200V individually controlled display dots. Bit map mode is selected by setting the BMM bit in register 17 (\$11) to a "1". The VIDEO MATRIX is still accessed as in character mode, but the video matrix data is no longer interpreted as character pointers, but rather as color data. The VIDEO MATRIX COUNTER is then also used as an address to fetch the dot data for display from the 3,000 byte DISPLAY BASE. The display base address is formed as follows:

A13	A12	A11	A10	A09	A08	A07	A06	A05	A04	A03	A02	A01	A00
C313	VC9	VC8	VC7	VC6	VC5	VC4	VC3	VC2	VC1	VC0	RC2	RC1	RC0

VCx denotes the video matrix counter outputs, RCx denotes the 3 bit raster line counter and C313 is from register 24 (\$13). The video matrix counter steps through the same 40 locations for eight raster lines, continuing to the next 40 locations every eighth line, while the raster counter increments once for each horizontal video line (raster line). This addressing results in each eight sequential memory

PROPRIETARY INFORMATION

COMMODORE INTL

13 MAY 1982

locations being formatted as an 8x8 dot block on the video display.

STANDARD BIT MAP MODE (BMM = 1, MCM = 0)

When standard bit map mode is in use, the color information is derived only from the data stored in the video matrix (the color nybble is disregarded). The 8 bits are divided into two 4-bit nybbles which allow two colors to be independently selected in each 8x8 dot block. When a bit in the display memory is a "0" the color of the output dot is set by the least significant (lower) nybble (LSN). Similarly, a display memory bit of "1" selects the output color determined by the MSN (upper nybble).

BIT	DISPLAY COLOR
0	Lower nybble of video matrix pointer
1	Upper nybble of video matrix pointer

MULTI-COLOR BIT MAP MODE (BMM = MCM = 1)

Multi-colored bit map mode is selected by setting the MCM bit in register 22 (\$16) to a "1" in conjunction with the BMM bit. Multi-color mode uses the same memory access sequence as standard bit map mode, but interprets the dot data as follows:

BIT PAIR	DISPLAY COLOR
00	Background #0 color (register 33 (\$21))
01	Upper nybble of video matrix pointer
10	Lower nybble of video matrix pointer
11	Video matrix color nybble

Note that the color nybble (\$B11-\$B3) is used for the multi-color bit map mode. Again, as two bits are used to select one dot color, the horizontal dot size is doubled, resulting in a screen resolution of 160H x 200V. Utilizing multi-color bit map mode, three independently selected colors can be displayed in each 8 x 8 block in addition to the background color.

PROPRIETARY INFORMATION

COMMODORE INTL

13 MAY 1982

MOVABLE OBJECT BLOCKS

The movable object block (MOB) is a special type of character which can be displayed at any one position on the screen without the block constraints inherent in character and bit map mode. Up to 8 unique MOBs can be displayed simultaneously, each defined by 63 bytes in memory which are displayed as a 24x21 dot array (shown below). A number of special features make MOBs especially suited for video graphics and game applications.

BYTE	BYTE	BYTE
00	01	02
03	04	05
.	.	.
.	.	.
57	58	59
60	61	62

MOB DISPLAY BLOCK

ENABLE

Each MOB can be selectively enabled for display by setting its corresponding enable bit (MnE) to "1" in register 21 (\$15). If the MnE bit is "0", no MOB operations will occur involving the disabled MOB.

POSITION

Each MOB is positioned via its X and Y position register (see register map) with a resolution of 512 horizontal and 256 vertical positions. The position of a MOB is determined by the upper-left corner of the array. X locations 24 to 343 (\$18-\$157) and Y locations 58 to 249 (\$32-\$F9) are visible. Since not all available MOB positions are entirely visible on the screen, MOBs may be moved smoothly on and off the display screen.

COLOR

Each MOB has a separate 4-bit register to determine the MOB color. The two MOB color modes are:

STANDARD MOB

(MnMC = 0)

In the standard mode, a "0" bit of MOB data allows any background data to show through (transparent) and a "1" bit is displayed as the MOB color determined by the corresponding MOB Color register.

PROPRIETARY INFORMATION COMMODORE INTL

13 MAY 1982

MULTI-COLOR MOB

(MnMC = 1)

Each MOB can be individually selected as a multi-color MOB via MnMC bits in the MOB Multi-color register 29 (\$10). When the MnMC bit is "1", the corresponding MOB is displayed in the multi-color mode. In the multi color mode, the MOB data is interpreted in pairs (similar to the other multi-color modes) as follows:

BIT PAIR	COLOR DISPLAYED
00	Transparent
01	MOB Multi-color #0 (register 37 (\$25))
10	MOB Color (registers 39-46 (\$27-\$2E))
11	MOB Multi-color #1 (register 38 (\$26))

Since two bits of data are required for each color, the resolution of the MOB is reduced to 12x21, with each horizontal dot expanded to twice standard size so that the overall MOB size does not change. Note that up to 3 colors can be displayed in each MOB (in addition to transparent) but that two of the colors are shared among all the MOBs in the multi-color mode.

MAGNIFICATION

Each MOB can be selectively expanded (2X) in both the horizontal and vertical directions. Two registers contain the control bits (MnXE, MnYE) for the magnification control:

REGISTER	FUNCTION
29 (\$10)	Horizontal expand MnXE - "1"=expand; "0"=normal
23 (\$17)	Vertical expand MnYE - "1"=expand; "0"=normal

When MOBs are expanded, no increase in resolution is realized. The same 24x21 array (12x21 if multi-colored) is displayed, but the overall MOB dimension is doubled in the desired direction (the smallest MOB dot may be up to 4X standard dot dimension if a MOB is both multi-colored and expanded).

PRIORITY

The priority of each MOB may be individually controlled with respect to the other displayed information from character or bit map modes. The priority of each MOB is set by the corresponding bit (MnOP) of register 27 (\$18) as follows:

REG BIT PRIORITY TO CHARACTER OR BIT MAP DATA

0 Non-transparent MOB data will be displayed (MOB in front)
1 Non-transparent MOB data will be displayed only instead of Bkgrd #0 or multi-color bit pair 01 (MOB behind)

PROPRIETARY INFORMATION

COMMODORE INTL

13 MAY 1982

MNOP = 1	MNOP = 0
MOBn	Foreground
Foreground	MOBn
Background	Background

MOB - DISPLAY DATA PRIORITY

MOB data bits of "0" ("00" in multi-color mode) are transparent, always permitting any other information to be displayed.

The MOB's have a fixed priority with respect to each other, with MOB 0 having the highest priority and MOB 7 the lowest. When MOB data (except transparent data) of two MOB's are co-incident, the data from the lower number MOB will be displayed. MOB vs. MOB data is prioritized before priority resolution with character or bit map data.

COLLISION DETECTION

Two types of MOB collision (co-incidence) are detected. MOB to MOB collision and MOB to display data collision:

A collision between two MOB's occurs when non-transparent output data of two MOB's are co-incident. Co-incidence of MOB transparent areas will not generate a collision. When a collision occurs, the MOB bits (MmM) in the MOB-MOB COLLISION register 30 (\$1E) will be set to "1" for both colliding MOB's. As a collision between two (or more) MOB's occurs, the MOB-MOB collision bit for each collided MOB will be set. The collision bits remain set until a read of the collision register, when all bits are automatically cleared. MOB's collisions are detected even if positioned off-screen.

The second type of collision is a MOB-ORATA collision between a MOB and foreground display data from the character or bit map modes. The MOB-ORATA COLLISION register 31 (\$1F) has a bit (MnQ) for each MOB which is set to "1" when both the MOB and non-background display data are co-incident. Again, the co-incidence of only transparent data does not generate a collision. For special applications, the display data from the 0.1 multicolor bit pair also does not cause a collision. This feature permits their use as background display data without interfering with true MOB collisions. A MOB-ORATA collision can occur off-screen in the horizontal direction if actual display data has been scrolled to an off-screen position (see scrolling). The MOB-ORATA COLLISION register also automatically clears when read.

The collision interrupt latches are set whenever the first bit of either register is set to "1". Once any collision bit within a register is set high, subsequent collisions will not set the interrupt latch until that collision register has been cleared to all "0"s by a read.

PROPRIETARY INFORMATION

COMMODORE INTL.

13 MAY 1982

MOB MEMORY ACCESS

The data for each MOB is stored in 63 consecutive bytes of memory. Each block of MOB data is defined by a MOB pointer, located at the end of the VIDEO MATRIX. Only 1,000 bytes of the video matrix are used in the normal display modes, allowing the video matrix locations 1016-1023 (VM base \$3F8 to VM base \$3FF) to be used for MOB pointers 0-7, respectively. The eight-bit MOB pointer from the video matrix together with the six bits from the MOB byte counter (to address 63 bytes) define the entire 14-bit address field:

A13	A12	A11	A10	A09	A08	A07	A06	A05	A04	A03	A02	A01	A00
MP7	MP6	MP5	MP4	MP3	MP2	MP1	MP0	MC5	MC4	MC3	MC2	MC1	MC0

Where MPx are the MOB pointer bits from the video matrix and MCx are the internally generated MOB counter bits. The MOB pointers are read from the video matrix at the end of every raster line. When the Y position register of a MOB matches the current raster line count, the actual fetches of MOB data begin. Internal counters automatically step through the 63 bytes of MOB data, displaying three bytes on each raster line.

OTHER FEATURES

SCREEN BLANKING

The display screen may be blanked by setting the DEN bit in register 17 (\$11) to a "0". When the screen is blanked, the entire screen will be filled with the exterior color as set in register 32 (\$28). When blanking is active, only transparent (Phase 1) memory accesses are required, permitting full processor utilization of the system bus. MOB data, however, will be accessed if the MOBS are not also disabled. The DEN bit must be set to "1" for normal video display.

ROW/COLUMN SELECT

The normal display consists of 25 rows of 40 characters (or character regions) per row. For special display purposes, the display window may be reduced to 24 rows and 33 characters. There is no change in the format of the displayed information, except that characters adjacent to the exterior border area will now be covered by the border. The select bits operate as follows:

RSEL	Number of rows	CSEL	Number of columns
0	24 rows	0	33 columns
1	25 rows	1	40 columns

The RSEL bit is in register 17 (\$11) and the CSEL bit is in register 22 (\$16). For standard display the larger display window is normally used, while the smaller display window is normally used in conjunction with scrolling.

PROPRIETARY INFORMATION

COMMODORE INTL

13 MAY 1982

SCROLLING

The display data may be scrolled up or down one character space in both the horizontal and vertical direction. When used in conjunction with the smaller display window (above), scrolling can be used to create a smooth panning motion of display data while updating the system memory only when a new character row (or column) is required. Scrolling is also used to center a fixed display within the display window.

BITS	REGISTER	FUNCTION
X2, X1, X0	22 (\$10)	Horizontal Position
Y2, Y1, Y0	17 (\$11)	Vertical Position

LIGHT PEN

The light pen input latches the current screen position into a pair of registers (LPX, LPY) on a low-going edge. The X position register 19 (\$13) will contain the 3 MSB of the X position at the time of transition.

The Y position is latched in its register 20 (\$14) but here 3 bits provide single raster resolution within the visible display. The light pen latch may be triggered only once per frame, and subsequent triggers within the same frame will have no effect.

RASTER REGISTER

The raster register is a dual function register. A read of the raster register 18 (\$12) returns the lower 3 bits of the current raster position (the MSB-RC3 is located in register 17 (\$11)). The raster register can be interrogated to implement display changes outside the visible area to prevent display flicker. The visible display window is from raster 50 through raster 249 (\$033-\$0FB). A write to the raster bits (including RC3) is latched for use in an internal raster compare. When the current raster matches the written value, the raster interrupt latch is set.

INTERRUPT REGISTER

The interrupt register shows the status of the four sources of interrupt. An interrupt latch in register 25 (\$19) is set to 1 when an interrupt source has generated an interrupt request. The four sources of interrupt are:

LATCH BIT	ENABLE BIT	WHEN SET
IRST	ERST	Set when (raster count) = (stored raster count)
IMOC	EMOC	Set by MOB-OBTA collision register (first collision only)
INMC	EMMC	Set by MOB-MOB collision register (first collision only)
ILP	ELP	Set by negative transition of LP input (once per frame)
IRQ		Set high by latch set and enabled (input of IRQ output)

PROPRIETARY INFORMATION

COMMODORE INTL

13 MAY 1982

To enable an interrupt request to set the IRQ_{OUT} output to "0", the corresponding interrupt enable bit in register 25 (31A) must be set to "1". Once an interrupt latch has been set, the latch can only be cleared only by writing a "1" to the desired latch in the interrupt register. This feature allows selective handling of video interrupts without software required to "remember" active interrupts.

DYNAMIC RAM REFRESH

A dynamic ram refresh controller is built in to the 6366/6367 devices. Five 8-bit row addresses are refreshed every raster line. This rate guarantees a maximum delay of 2.02 ms between the refresh of any single row address in a 128 refresh scheme. (The maximum delay is 3.66ms in a 256 address refresh scheme). This refresh is totally transparent to the system, since the refresh occurs during Phase 1 of the system clock. The 6367 generates both RAS_{OUT} and CAS_{OUT} which are normally connected directly to the dynamic rams. RAS_{OUT} and CAS_{OUT} are generated for every Phase 2 and every video data access (including refresh) so that external clock generation is not required.

RESET

The reset bit (RES) in register 22 (31E) is not used for normal operation. Therefore it should be set to "0" when initializing the video chip. When set to a "1", the entire operation of the video chip is suspended, including video outputs and sync, memory refresh, and system bus access.

THEORY OF OPERATION

SYSTEM INTERFACE

The 6366/6367 video controller devices interact with the system data bus in a special way. A 65XX system requires the system busses only during the Phase 2 (clock high) portion of the cycle. The 6366/6367 devices take advantage of this feature by normally accessing system memory during the Phase 1 (clock low) portion of the clock cycle. Therefore, operations such as character data fetches and memory refresh are totally transparent to the processor and do not reduce the processor through-put. The video chips provide the interface control signals required to maintain this bus sharing.

The video devices provide the signal REC (address enable control) which is used to disable the processor address bus drivers allowing the video device to access the address bus. REC is active low which permits direct connection to the REC input of the 65XX family. The REC signal is normally activated during Phase 1 so that processor operation is not affected. Because of this bus "sharing", all memory accesses must be completed in 1/2 cycle. Since the video chips provide a 1MHz clock (which must be used as system Phase 2), a memory cycle is 500ns including address setup, data access and data setup to the reading device.

Certain operations of the 6366/6367 require data at a faster rate than available by reading only during the Phase 1 time; specifically, the access of character pointers from the video matrix and the fetch of MOB data. Therefore, the processor must be disabled and the data accessed during the Phase 2 clock. This is accomplished via the BA (bus available) signal. The BA line is normally high but is brought low during Phase 1 to indicate that the video chip will require a Phase 2 data access. Three Phase 2 times are allowed after BA low for the processor to complete any current memory accesses. On the fourth Phase 2 after BA low, the REC signal will remain low during Phase 2 as the video chip fetches data. The BA line is normally connected to the RDY No. input of a 63XX processor. The character pointer fetches occur every eighth raster line during the display window and require 40 consecutive Phase 2 accesses to fetch the video matrix pointers. The MOB data fetches require 4 memory accesses as follows:

PHASE	DATA	CONDITION
1	MOB Pointer	Every raster
2	MOB Byte 1	Each raster while MOB is displayed
2	MOB Byte 2	Each raster while MOB is displayed
2	MOB Byte 3	Each raster while MOB is displayed

The MOB pointers are fetched every other Phase 1 at the end of each raster line. As required, the additional cycles are used for MOB data fetches. Again, all necessary bus control is provided by the 6366/6367 devices.

MEMORY INTERFACE

The two versions of the video interface chip, 6366 and 6367, differ in address output configurations. The 6366 has thirteen fully decoded addresses for direct connection to the system address bus. The 6367 has multiplexed addresses for direct connection to 64K dynamic RAMs. The least significant address bits, A05-A00, are present on A05-A00 while RAS is brought low, while the most significant bits, A13-A08, are present on A05-A00 while CAS is brought low. The pins A11-A07 on the 6367 are static address outputs to allow direct connection of these bits to a conventional 16K (2Kx3) ROM. (The lower order addresses require external latching).

PROCESSOR INTERFACE

Aside from the special memory accesses described above, the 6366/6367 registers can be accessed similar to any other peripheral device. The following processor interface signals are provided:

DATA-BUS (DB7-DB0) - 8-bit data bus, bidirectional, controlled by CS/RW, and Phase 0. The data bus can only be accessed while REC and Phase 0 are high and CS is low.

The eight data bus pins are the bi-directional data port, controlled by CS/RW, and Phase 0. The data bus can only be accessed while REC and Phase 0 are high and CS is low.

CHIP SELECT (CS/)

The chip select pin, CS/, is brought low to enable access to the device registers in conjunction with the address and RW pins. CS/ low is recognized only while AEC and Phase 0 are high.

READ/WRITE (R/W)

The read/write input, R/W, is used to determine the direction of data transfer on the data bus, in conjunction with CS/. When R/W is high ("1") data is transferred from the selected register to the data bus output. When R/W is low ("0") data presented on the data bus pins is loaded into the selected register.

ADDRESS BUS (A05-A00)

The lower six address pins, A5-A0, are bi-directional. During a processor read or write of the video device, these address pins are inputs. The data on the address inputs selects the register for read or write as defined in the register map.

CLOCK OUT (PH0)

The clock output, Phase 0, is the 1MHz clock used as the 65XX processor Phase 0 in. All system bus activity is referenced to this clock. The clock frequency is generated by dividing the 3MHz video input clock by eight.

INTERERRUPTS (IRQ/)

The interrupt output, IRQ/, is brought low when an enabled source of interrupt occurs within the device. The IRQ/ output is open drain, requiring an external pull-up resistor.

VIDEO INTERFACE

The video output signal from the 6566/6567 consists of two signals which must be externally mixed together. SYNC/LUM output contains all the video data, including horizontal and vertical syncs, as well as the luminance information of the video display. SYNC/LUM is open drain, requiring an external pullup of 500 ohms. The COLOR output contains all the chrominance information, including the color reference burst and the color of all display data. The COLOR output is open source and should be terminated with 1,000 ohms to ground. After appropriate mixing of these two signals, the resulting signal can directly drive a video monitor or be fed to a modulator for use with a standard television.

REC	PH0	CS/	R/W	ACTION
0	0	X	X	PHASE 1 FETCH, REFRESH
0	1	X	X	PHASE 2 FETCH (PROCESSOR OFF)
1	0	X	X	NO ACTION
1	1	0	0	WRITE TO SELECTED REGISTER
1	1	0	1	READ FROM SELECTED REGISTER
1	1	1	X	NO ACTION

SUMMARY OF 6566/6567 BUS ACTIVITY

(6566/6567) BUS ACTIVITY

1. The 6566/6567 bus is a 16-bit parallel bus. It is used to transfer data between the processor and the memory. The bus is divided into two sections: the address bus and the data bus. The address bus is used to transfer the address of the memory location to be accessed. The data bus is used to transfer the data from the memory location to the processor or vice versa.

(6566/6567) BUS ACTIVITY

2. The 6566/6567 bus is a synchronous bus. This means that all data transfers are synchronized to a common clock signal. The clock signal is provided by the processor. The bus is divided into two sections: the address bus and the data bus. The address bus is used to transfer the address of the memory location to be accessed. The data bus is used to transfer the data from the memory location to the processor or vice versa.

(6566/6567) BUS ACTIVITY

3. The 6566/6567 bus is a full-duplex bus. This means that data can be transferred in both directions at the same time. The address bus is used to transfer the address of the memory location to be accessed. The data bus is used to transfer the data from the memory location to the processor or vice versa.

(6566/6567) BUS ACTIVITY

4. The 6566/6567 bus is a high-speed bus. It is capable of transferring data at a rate of up to 100 MB/s. The bus is divided into two sections: the address bus and the data bus. The address bus is used to transfer the address of the memory location to be accessed. The data bus is used to transfer the data from the memory location to the processor or vice versa.

6581 SOUND INTERFACE DEVICE (SID)

CONCEPT

The 6581 Sound Interface Device (SID) is a single-chip, 3-device electronic music synthesizer/sound effects generator compatible with the 6500 and similar microprocessor families. SID provides wide-range, high-resolution control of pitch (frequency), tone color (harmonic content), and dynamics (volume). Specialized control circuitry minimizes software overhead, facilitating use in arcade/home video games and low-cost musical instruments.

FEATURES

- 3 TONE OSCILLATORS
 - Range: 0-4 kHz
- 4 WAVEFORMS PER OSCILLATOR
 - Triangle, Sawtooth, Variable Pulse, Noise
- 3 AMPLITUDE MODULATORS
 - Range: 48 dB
- 3 ENVELOPE GENERATORS
 - Exponential response
 - Attack Rate: 2ms-8s
 - Decay Rate: 6ms-24s
 - Sustain Level: 0-peak volume
 - Release Rate: 6ms-24s

OSCILLATOR SYNCHRONIZATION

RING MODULATION

PROGRAMMABLE FILTER

- Cutoff range: 30 Hz-12 kHz
- 12 dB/octave rolloff
- Low pass, Band pass, High pass, Notch outputs
- Variable Resonance

DESCRIPTION

The SID consists of three synthesizer voices which can be used independently or in conjunction with each other (or external audio sources) to create complex sounds. Each voice consists of a Tone Oscillator/Waveform Generator, an Envelope Generator and an Amplitude Modulator. The Tone Oscillator controls the pitch of the voice over a wide range. The Oscillator produces four waveforms at the selected frequency, with the unique harmonic content of each waveform providing simple control of tone color. The volume dynamics of the Oscillator are controlled by the Amplitude Modulator under the direction of the Envelope Generator. When triggered, the Envelope Generator creates an amplitude envelope with programmable rates of increasing and decreasing volume. In addition to the three voices, a programmable Filter is provided for generating complex, dynamic tone colors via subtractive synthesis.

SID allows the microprocessor to read the changing output of the third Oscillator and third Envelope Generator. These outputs can be used as a source of modulation information for creating vibrato, frequency/filter sweeps and similar effects. The third oscillator can also act as a random number generator for games. Two A/D converters are provided for interfacing SID with potentiometers. These can be used for "paddles" in a game environment or as front panel controls in a music synthesizer. SID can process external audio signals, allowing multiple SID chips to be daisy-chained or mixed in complex polyphonic systems.

54075-11020 5407 5

6531 SID BLOCK DIAGRAM

SID CONTROL REGISTERS

There are 28 eight-bit registers in SID which control the generation of sound. These registers are either WRITE-only or READ-only, and are listed below in Table 1.

ADDRESS					REG #	DATA								REG NAME	REG TYPE

TABLE 1 - SID REGISTER MAP

VOICE 1 FREQ & PW (Registers 00, 01)

FREQ LO/FREQ HI (Registers 00, 01)

Together these registers form a 16-bit number which linearly controls the frequency of Oscillator 1. The frequency is determined by the following equation:

$$F_{out} = (Fn * F_{clk} / 16777216) \text{ Hz}$$

Where Fn is the 16-bit number in the Frequency registers and F_{clk} is the system clock applied to the 02 input (pin 5). For a standard 1.0 MHz clock, the frequency is given by:

$$F_{out} = (Fn * 0.0596) \text{ Hz}$$

A complete table of values for generating 3 octaves of the equally-tempered musical scale with concert A (440 Hz) tuning is provided in appendix A. It should be noted that the frequency resolution of SID is sufficient for any tuning scale and allows sweeping from note to note (portamento) with no discernable frequency steps.

PW LO/PW HI (Registers 02, 03)

Together these registers form a 12-bit number (bits 4-7 of PW HI are not used) which linearly controls the Pulse Width (duty cycle) of the Pulse waveform on Oscillator 1. The pulse width is determined by the following equation:

$$PW_{out} = (PWN / 4095) \%$$

Where PWN is the 12-bit number in the Pulse Width registers.

The pulse width resolution allows the width to be smoothly swept with no discernable stepping. Note that the Pulse waveform on Oscillator 1 must be selected in order for the Pulse Width registers to have any audible effect. A value of 0 or 4095 (FFFF) in the Pulse Width registers will produce a constant DC output, while a value of 2048 (8000) will produce a square wave.

CONTROL REGISTER (Register 04)

This register contains eight control bits which select various options on Oscillator 1.

GATE (Bit 0) - The GATE bit controls the Envelope Generator for Voice 1. When this bit is set to a one, the Envelope Generator is Gated (triggered) and the ATTACK/DECAY/SUSTAIN cycle is initiated. When the bit is reset to a zero, the RELEASE cycle begins. The Envelope Generator controls the amplitude of Oscillator 1 appearing at the audio output; therefore, the GATE bit must be set (along with suitable envelope parameters) for the selected output of Oscillator 1 to be audible. A detailed discussion of the Envelope Generator can be found in Appendix B.

SYNC (Bit 1) - The SYNC bit, when set to a one, synchronizes the fundamental frequency of Oscillator 1 with the fundamental frequency of Oscillator 3, producing "Hard Sync" effects. Varying the frequency of Oscillator 1 with respect to Oscillator 3 produces a wide range of complex harmonic structures from Voice 1 at the frequency of Oscillator 3. In order for sync to occur, Oscillator 3 must be set to some frequency other than zero but preferably lower than the frequency of Oscillator 1. No other parameters of Voice 3 have any effect on sync.

RING MOD (Bit 2) - The RING MOD bit, when set to a one, replaces the Triangle waveform output of Oscillator 1 with a "Ring Modulation" combination of Oscillators 1 and 3. Varying the frequency of Oscillator 1 with respect to Oscillator 3 produces a wide range of non-harmonic overtone structures for creating bell or gong sounds and for special effects. In order for ring modulation to be audible, the Triangle waveform of Oscillator 1 must be selected and Oscillator 3 must be set to some frequency other than zero. No other parameters of Voice 3 have any effect on ring modulation.

TEST (Bit 3) - The TEST bit, when set to a one, resets and locks Oscillator 1 at zero until the TEST bit is cleared. The Noise waveform output of Oscillator 1 is also reset and the Pulse waveform output is held at a DC level. Normally this bit is used for testing purposes; however, it can be used to synchronize Oscillator 1 to external events, allowing the generation of highly complex waveforms under real-time software control.

 **(Bit 4)** - When set to a one, the Triangle waveform output of Oscillator 1 is selected. The Triangle waveform is low in harmonics and has a mellow, flute-like quality.

 **(Bit 5)** - When set to a one, the Sawtooth waveform output of Oscillator 1 is selected. The Sawtooth waveform is rich in even and odd harmonics and has a bright, brassy quality.

 **(Bit 6)** - When set to a one, the Pulse waveform output of Oscillator 1 is selected. The harmonic content of this waveform can be adjusted by the Pulse Width registers, producing tone qualities ranging from a bright, hollow square wave to a nasal, reedy pulse. Sweeping the pulse width in real-time produces a dynamic "phasing" effect which adds a sense of motion to the sound. Rapidly jumping between different pulse widths can produce interesting harmonic sequences.

NOISE (Bit 7) - When set to a one, the Noise output waveform of Oscillator 1 is selected. This output is a random signal which changes at the frequency of Oscillator 1. The sound quality can be varied from a low rumbling to hissing white noise via the Oscillator 1 Frequency registers. Noise is useful in creating explosions, gunshots, jet engines, wind, surf and other unpitched sounds, as well as snare drums and cymbals. Sweeping the oscillator frequency with Noise selected produces a dramatic rushing effect.

One of the output waveforms must be selected for Oscillator 1 to be audible; however, it is NOT necessary to deselect waveforms to silence the output of Voice 1. The amplitude of Voice 1 at the final output is a function of the Envelope Generator only.

NOTE: The oscillator output waveforms are NOT additive. If more than one output waveform is selected simultaneously, the result will be a logical ANDing of the waveforms. Although this technique can be used to generate additional waveforms beyond the four listed above, it must be used with care. If any other waveform is selected while Noise is on, the Noise output can "lock up". If this occurs, the Noise output will remain silent until reset by the TEST bit or by bringing REG (pin 5) low.

ATTACK/DECAY (Register 05) -

Bits 4-7 of this register (ATK0-ATK3) select 1 of 16 ATTACK rates for the Voice 1 Envelope Generator. The ATTACK rate determines how rapidly the output of Voice 1 rises from zero to peak amplitude when the Envelope Generator is Gated. The 16 ATTACK rates are listed below in Table 2.

Bits 8-3 (DCY0-DCY3) select 1 of 16 DECAY rates for the Envelope Generator. The DECAY cycle follows the ATTACK cycle and the DECAY rate determines how rapidly the output falls from the peak amplitude to the selected SUSTAIN level. The 16 DECAY rates are listed in Table 2.

SUSTAIN/RELEASE (Register 06) -

Bits 4-7 of this register (STN0-STN3) select 1 of 16 SUSTAIN levels for the Envelope Generator. The SUSTAIN cycle follows the DECAY cycle and the output of Voice 1 will remain at the selected SUSTAIN amplitude as long as the Gate bit remains set. The SUSTAIN levels range from zero to peak amplitude in 16 linear steps, with a SUSTAIN value of 0 selecting zero amplitude and a SUSTAIN value of 15 selecting the peak amplitude. A SUSTAIN value of 8 would cause Voice 1 to SUSTAIN at an amplitude one-half the peak amplitude reached by the ATTACK cycle.

Bits 8-3 (RLS0-RLS3) select 1 of 16 RELEASE rates for the Envelope Generator. The RELEASE cycle follows the SUSTAIN cycle when the Gate bit is reset to zero. At this time, the output of Voice 1 will fall from the SUSTAIN amplitude to zero amplitude at the selected RELEASE rate. The 16 RELEASE rates are identical to the DECAY rates.

NOTE: The cycling of the Envelope Generator can be altered at any point via the Gate bit. The Envelope Generator can be Gated and Released without restriction. For example, if the Gate bit is reset before the envelope has finished the ATTACK cycle, the RELEASE cycle will immediately begin, starting from whatever amplitude had been reached. If the envelope is then Gated again (before the RELEASE cycle has reached zero amplitude), another ATTACK cycle will begin, starting from whatever amplitude had been reached. This technique can be used to generate complex amplitude envelopes via real-time software control.

TABLE 2 - ENVELOPE RATES

VALUE	ATTACK RATE	DECAY/RELEASE RATE
DEC (HEX)	(Time/Cycle)	(Time/Cycle)
0 (0)	2 MS	6 MS
1 (1)	8 MS	24 MS
2 (2)	16 MS	48 MS
3 (3)	24 MS	72 MS
4 (4)	32 MS	114 MS
5 (5)	56 MS	168 MS
6 (6)	68 MS	204 MS
7 (7)	88 MS	240 MS
8 (8)	100 MS	300 MS
9 (9)	250 MS	750 MS
10 (A)	500 MS	1.5 S
11 (B)	800 MS	2.4 S
12 (C)	1 S	3 S
13 (D)	3 S	9 S
14 (E)	5 S	15 S
15 (F)	8 S	24 S

NOTE: Envelope rates are based on a 1.0 MHz 82 clock. For other 82 frequencies, multiply the given rate by 1 MHz/82. The rates refer to the amount of time per cycle. For example, given an ATTACK value of 2, the ATTACK cycle would take 16 ms to rise from zero to peak amplitude. The DECAY/RELEASE rates refer to the amount of time these cycles would take to fall from peak amplitude to zero.

Registers #07-#09 control Voice 2 and are functionally identical to registers #00-#02 with these exceptions:

- When selected, SYNC synchronizes Oscillator 2 with Oscillator 1.
- When selected, RING MOD replaces the Triangle output of Oscillator 2 with the ring modulated combination of Oscillators 2 and 1.

VOICE 3

Registers #0E-#14 control Voice 3 and are functionally identical to registers #00-#06 with these exceptions:

- When selected, SYNC synchronizes Oscillator 3 with Oscillator 2.
- When selected, RING MOD replaces the Triangle output of Oscillator 3 with the ring modulated combination of Oscillators 3 and 2.

Typical operation of a voice consists of selecting the desired parameters frequency, waveform, effects (SYNC, RING MOD) and envelope rates, then gating the voice whenever the sound is desired. The sound can be sustained for any length of time and terminated by clearing the Gate bit. Each voice can be used separately, with independent parameters and gating, or in unison to create a single, powerful voice. When used in unison, a slight detuning of each oscillator or tuning to musical intervals creates a rich, animated sound.

FILTER

FC LO/FC HI (Registers #15, #16) -

Together these registers form an 11-bit number (bits 3-7 of FC LO are not used) which linearly controls the Cutoff (or Center) Frequency of the programmable Filter. The approximate Cutoff Frequency is determined by the following equation:

$$FC_{out} = ((6.6E-9 + FC_n * 1.29E-9)/C) \text{ Hz}$$

Where FC_n is the 11-bit number in the Cutoff registers and C is the value of the two Filter capacitors connected to pins 1-4. For the recommended capacitor value of 2200 pF, the approximate range of the Filter is 30 Hz-125 kHz according to the following equation:

$$FC_{out} = (30 + FC_n * 5.8) \text{ Hz}$$

The frequency range of the Filter can be altered to suit specific applications. Refer to the Pin Description section for more information.

RES/FILT (Register #17) -

Bits 4-7 of this register (RES0-RES3) control the Resonance of the Filter. Resonance is a peaking effect which emphasizes frequency components at the Cutoff Frequency of the Filter, causing a sharper sound. There are 16 Resonance settings ranging linearly from no resonance (0) to maximum resonance (15 or SF).

Bits 0-3 determine which signals will be routed through the Filter:

FILT 1 (Bit 0) - When set to a zero, Voice 1 appears directly at the audio output and the Filter has no effect on it. When set to a one, Voice 1 will be processed through the Filter and the harmonic content of Voice 1 will be altered according to the selected Filter parameters.

FILT 2 (Bit 1) - Same as bit 0 for Voice 2.

FILT 3 (Bit 2) - Same as bit 0 for Voice 3.

FILTEX (Bit 3) - Same as bit 0 for External audio input (pin 26).

MODE/VOL (Register 218)

Bits 4-7 of this register select various Filter mode and output options:

LP (Bit 4) - When set to a one, the Low Pass output of the Filter is selected and sent to the audio output. For a given Filter input signal, all frequency components below the Filter Cutoff Frequency are passed unaltered, while all frequency components above the Cutoff are attenuated at a rate of 12 dB/Octave. The Low Pass mode produces full-bodied sounds.

BP (Bit 5) - Same as bit 4 for the Band Pass output. All frequency components above and below the Cutoff are attenuated at a rate of 6 dB/Octave. The Band Pass mode produces thin, open sounds.

HP (Bit 6) - Same as bit 4 for the High Pass output. All frequency components above the Cutoff are passed unaltered, while all frequency components below the Cutoff are attenuated at a rate of 12 dB/Octave. The High Pass mode produces tinny, buzzy sounds.

3 OFF (Bit 7) - When set to a one, the output of Voice 3 is disconnected from the direct audio path. Setting Voice 3 to bypass the Filter (FILT 3=0) and setting 3 OFF to a one prevents Voice 3 from reaching the audio output. This allows Voice 3 to be used for modulation purposes without any undesirable output. More information on modulation effects can be found in Appendix C.

NOTE: The Filter output modes ARE additive and multiple Filter modes may be selected simultaneously. For example, both LP and HP modes can be selected to produce a Notch (or Band Reject) Filter response. In order for the Filter to have any audible effect, at least one Filter output must be selected and at least one Voice must be routed through the Filter. The Filter is, perhaps, the most important element in SID synthesis (the Filter is used to eliminate specific frequency components from a harmonically-rich input signal). The best results are achieved by varying the Cutoff Frequency in real-time. Further discussion of the Filter appears in Appendix C.

Bits 8-3 (VOL0-VOL3) select 1 of 16 overall Volume levels for the final composite audio output. The output volume levels range from no output (0) to a static volume control for balancing levels in multi-chip systems or for creating dynamic volume effects, such as Tremolo. Some Volume level other than zero must be selected in order for SID to produce any sound.

MISC

POTX (Register \$19) -

This register allows the microprocessor to read the position of the potentiometer tied to POTX (pin 24), with values ranging from 0 at minimum resistance, to 255 (\$FF) at maximum resistance. The value is always valid and is updated every 512 82 clock cycles. See the Pin Description section for information on pot and capacitor values.

POTY (Register \$1A) -

Same as POTX for the pot tied to POTY (pin 23).

OSC 3/RANDOM (Register \$1B) -

This register allows the microprocessor to read the upper 8 output bits of Oscillator 3. The character of the numbers generated is directly related to the waveform selected. If the Sawtooth waveform of Oscillator 3 is selected, this register will present a series of numbers incrementing from 0 to 255 (\$FF) at a rate determined by the frequency of Oscillator 3. If the Triangle waveform is selected, the output will increment from 0 up to 255, then decrement down to 0. If the Pulse waveform is selected, the output will jump between 0 and 255. Selecting the Noise waveform will produce a series of random numbers, therefore, this register can be used as a random number generator for games. There are numerous timing and sequencing applications for the OSC 3 register, however, the chief function is probably that of a modulation generator. The numbers generated by this register can be added, via software, to the Oscillator or Filter Frequency registers or the Pulse Width registers in real-time. Many dynamic effects can be generated in this manner. Siren-like sounds can be created by adding the OSC 3 Sawtooth output to the frequency control of another oscillator. Synthesizer "Sample and Hold" effects can be produced by adding the OSC 3 Noise output to the Filter Frequency control registers. Vibrato can be produced by setting Oscillator 3 to a frequency around 7 Hz and adding the OSC 3 Triangle output (with proper scaling) to the frequency control of another oscillator. An unlimited range of effects are available by altering the frequency of Oscillator 3 and scaling the OSC 3 output. Normally, when Oscillator 3 is used for modulation, the audio output of Voice 3 should be eliminated (3 OFF=1).

ENV 3 (Register \$1C) -

Same as OSC 3, but this register allows the microprocessor to read the output of the Voice 3 Envelope Generator. This output can be added to the Filter Frequency to produce harmonic envelopes, WAH WAH, and similar effects. "Phaser" sounds can be created by adding this output to the frequency control registers of an oscillator. The Voice 3 Envelope Generator must be Gated in order to produce any output from this register. The OSC 3 register, however, always reflects the changing output of the oscillator and is not affected in any way by the Envelope Generator. Further information on modulation can be found in Appendix C.

SID PIN-DESCRIPTION

CAP1A, CAP1B (Pins 1, 2) & CAP2A, CAP2B (Pins 3, 4) - These pins are used to connect the two integrating capacitors required by the programmable Filter. C1 connects between pins 1 and 2 & C2 between pins 3 and 4. Both capacitors should be the same value. Normal operation of the Filter over the audio range (approximately 20 Hz to 12 kHz) is accomplished with a value of 2200 pF for C1 and C2. Polystyrene capacitors are preferred and in complex polyphonic systems, where many SID chips must track each other, matched capacitors are recommended. The frequency range of the Filter can be tailored to specific applications by the choice of capacitor values. For example, a low-cost game may not require full high-frequency response. In this case, larger values for C1 and C2 could be chosen to provide more control over the bass frequencies of the Filter. The maximum Cutoff Frequency of the Filter is given by:

$$FC_{max} = 2.62 \times 10^5 / C$$

Where C is the capacitor value. The range of the Filter extends 9 octaves below the maximum Cutoff Frequency.

RES (Pin 5) - This TTL-level input is the reset control for SID. When brought low for at least ten 82 cycles, all internal registers are reset to zero and the audio output is silenced. This pin is normally connected to the reset line of the microprocessor or a power-on-clear circuit.

82 (Pin 6) - This TTL-level input is the master clock for SID. All oscillator frequencies and envelope rates are referenced to this clock. 82 also controls data transfers between SID and the microprocessor. Data can only be transferred when 82 is high. Essentially, 82 acts as a high-active chip select as far as data transfers are concerned. This pin is normally connected to the system clock, with a nominal operating frequency of 1.8 MHz.

R/W (Pin 7) - This TTL-level input controls the direction of data transfers between SID and the microprocessor. If the chip select conditions have been met, a high on this line allows the microprocessor to Read data from the selected SID register and a low allows the microprocessor to Write data into the selected SID register. This pin is normally connected to the system Read/Write line.

CS (Pin 8) - This TTL-level input is a low active chip select which controls data transfers between SID and the microprocessor. CS must be low for any transfer. A Read from the selected SID register can only occur if CS is low, 82 is high and R/W is high. A Write to the selected SID register can only occur if CS is low, 82 is high and R/W is low. This pin is normally connected to address decoding circuitry, allowing SID to reside in the memory map of a system.

A0-A4 (Pins 9-13) - These TTL-level inputs are used to select one of the 32 SID registers. Although enough addresses are provided to select 1 of 32 registers, the remaining three register locations are not used. A Write to any of these three locations is ignored and a Read returns invalid data. These pins are normally connected to the corresponding address lines of the microprocessor so that SID may be addressed in the same manner as memory.

GND (Pin 14) - For best results, the ground line between SID and the power supply should be separate from ground lines to other digital circuitry. This will minimize digital noise at the audio output.

IO (Pins 15-22) - These bidirectional lines are used to transfer data between SID and the microprocessor. They are TTL compatible in the output mode and capable of driving 2 TTL loads in the output mode. The data buffers are usually in the high-impedance-off-state. During a read operation, the data buffers remain in the off (input) state and the microprocessor supplies data to SID over these lines. During a write operation, the data buffers turn on and SID supplies data to the microprocessor over these lines. The pins are normally connected to the corresponding data lines of the microprocessor.

POTX, POTY (Pins 24, 25) - These pins are inputs to the A/D converters used to digitize the position of potentiometers. The conversion process is based on the time constant of a capacitor tied from the POT pin to ground, charged by a potentiometer tied from the POT pin to +5 volts. The component values are determined by:

$$RC = 4.7E-4$$

Where R is the maximum resistance of the pot and C is the capacitor. The larger the capacitor, the smaller the POT value jitter. The recommended values for R and C are 470 KOhms and 1000 pF. Note that a separate pot and cap are required for each POT pin.

VCC (Pin 26) - As with the GND line, a separate +5 VDC line should be run between SID Vcc and the power supply in order to minimize noise. A bypass capacitor should be located close to the pin.

EXT IN (Pin 26) - This analog input allows external audio signals to be mixed with the audio output of SID or processed through the Filter. Typical sources include voice, guitar, and organ. The input impedance of this pin is of the order of 100 KOhms. Any signal applied directly to the pin should ride at a DC level of 5 volts and should not exceed 3 volts p-p. In order to prevent any interference caused by DC level differences, external signals should be AC-coupled to EXT IN by an electrolytic capacitor in the 1-10 uF range. As the direct audio path (FILTEX=0) has unity gain, EXT IN can be used to mix outputs of many SID chips by daisy-chaining. The number of chips that can be chained in this manner is determined by the amount of noise and distortion allowable at the final output. Note that the output Volume control will affect not only the three SID voices, but also any external inputs.

AUDIO OUT (Pin 27) - This open-source buffer is the final audio output of SID, comprised of the three SID voices, the Filter and any external input. The output level is set by the output Volume control and reaches a maximum of 2 volts p-p at a DC level of 5 volts. A source resistor from AUDIO OUT to ground is required for proper operation. The recommended resistance is 1 KOhm for a standard output impedance. As the output of SID rides at a 5 volt DC level, it should be AC-coupled to any audio amplifier with an electrolytic capacitor in the 1-10 uF range.

VDD (Pin 28) - As with Vcc, a separate +12 VDC line should be run to SID Vdd and a bypass capacitor should be used.

COMMENT

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only. Functional operation of this device at these or any other conditions above those indicated in the operational sections of this specification is not implied and exposure to absolute maximum rating conditions for extended periods may affect device reliability.

All inputs contain protection circuitry to prevent damage due to high static discharges. Care should be exercised to prevent unnecessary application of voltages in excess of the allowable limits.

5581 SID TIMING

APPENDIX A - EQUAL-TEMPERED MUSICAL SCALE VALUES

The following table lists the numerical values which must be stored in the SID Oscillator frequency control registers to produce the notes of the equal-tempered musical scale. The equal-tempered scale consists of an octave containing 12 semitones (notes): C, D, E, F, G, A, B and C#, D#, E#, F#, G#, A#. The frequency of each semitone is exactly the 12th root of 2 ($\sqrt[12]{2}$) times the frequency of the previous semitone. The table is based on a 60 clock of 1.02 Mhz. Refer to the equation given in the Register Description for use of other master clock frequencies. The scale selected is concert pitch, in which A4 = 440 Hz. Transpositions of this scale and scales other than the equal-tempered scale are also possible.

	MUSICAL NOTE	FREQ (Hz)	OSC F _n (Decimal)	OSC F _n (Hex)
0	C0	16.35	269	0100
1	C0#	17.32	285	0110
2	D0	18.35	302	012E
3	D0#	19.45	320	0140
4	E0	20.60	339	0153
5	F0	21.83	359	0167
6	F0#	23.12	380	017C
7	G0	24.50	403	0193
8	G0#	25.96	427	01AB

Although the table above provides a simple and quick method for generating the equal-tempered scale, it is very memory inefficient as it requires 192 bytes for the table alone. Memory efficiency can be improved by determining the note value algorithmically. Using the fact that each note in an octave is exactly half the frequency of that note in the next octave, the note look-up table can be reduced from 96 entries to 12 entries, as there are 12 notes per octave. If the 12 entries (24 bytes) consist of the 16-bit value for the eighth octave (C7 through B7), then notes in lower octaves can be derived by choosing the appropriate note in the eighth octave and dividing the 16-bit value by two for each octave of difference. As division by two is nothing more than a right-shift of the value, the calculation can easily be accomplished by a simple software routine. Although note B7 is beyond the range of the Oscillators, this value should still be included in the table for calculation purposes (the MSB of B7 would require a special software case, such as generating this bit in the CARRY before shifting). Each note must be specified in a form which indicates which of the 12 semitones is desired, and which of the eight octaves the semitone is in. Since four bits are necessary to select 1 of 12 semitones and three bits are necessary to select 1 of 8 octaves, the information can fit in one byte, with the lower nybble selecting the semitone (by addressing the look-up table) and the upper nybble being used by the division routine to determine how many times the table value must be right-shifted.

APPENDIX B - SID ENVELOPE GENERATORS

The four-part ADSR (ATTACK, DECAY, SUSTAIN, RELEASE) envelope generator has been proven in electronic music to provide the optimum trade-off between flexibility and ease of amplitude control. Appropriate selection of envelope parameters allows the simulation of a wide range of percussion and sustained instruments. The violin is a good example of a sustained instrument. The violinist controls the volume by bowing the instrument. Typically, the volume builds slowly, reaches a peak, then drops to an intermediate level. The violinist can maintain this level for as long as desired, then the volume is allowed to slowly die away. A "snapshot" of this envelope is shown below:

This volume envelope can be easily reproduced by the ADSR as shown below, with typical envelope rates:

ATTACK: 10 (SR) 500 MS
 DECAY: 9 300 MS
 SUSTAIN: 10 (SR)
 RELEASE: 9 750 MS

Note that the tone can be held at the intermediate SUSTAIN level for as long as desired. The tone will not begin to die away until GATE is cleared. With minor alterations, this basic envelope can be used for brass and woodwinds as well as strings.

An entirely different form of envelope is produced by percussion instruments such as drums, cymbals and gongs, as well as certain keyboards such as pianos and harpsichords. The percussion envelope is characterized by a nearly instantaneous attack, immediately followed by a decay to zero volume. Percussion instruments cannot be sustained at a constant amplitude. For example, the instant a drum is struck, the sound reaches full volume and decays rapidly regardless of how it was struck. A typical cymbal envelope is shown below:

ATTACK: 0 2 MS
 DECAY: 9 750 MS
 SUSTAIN: 0
 RELEASE: 9 750 MS

Note that the tone immediately begins to decay to zero amplitude after the peak is reached, regardless of when GATE is cleared. The amplitude envelope of pianos and harpsichords is somewhat more complicated, but can be generated quite easily with the ADSR. These instruments reach full volume when a key is first struck. The amplitude immediately begins to die away slowly as long as the key remains depressed. If the key is released before the sound has fully died away, the amplitude will immediately drop to zero. This envelope is shown below:

ATTACK: 0 2 MS
 DECAY: 9 750 MS
 SUSTAIN: 0
 RELEASE: 0 5 MS

Note that the tone decays slowly until GATE is cleared, at which point the amplitude drops rapidly to zero.

The most simple envelope is that of the organ. When a key is pressed, the tone immediately reaches full volume and remains there. When the key is released, the tone drops immediately to zero volume. This envelope is shown below:

ATTACK: 0 2 mS
 DECAY: 0 6 mS
 SUSTAIN: 15 (SF)
 RELEASE: 0 6 mS

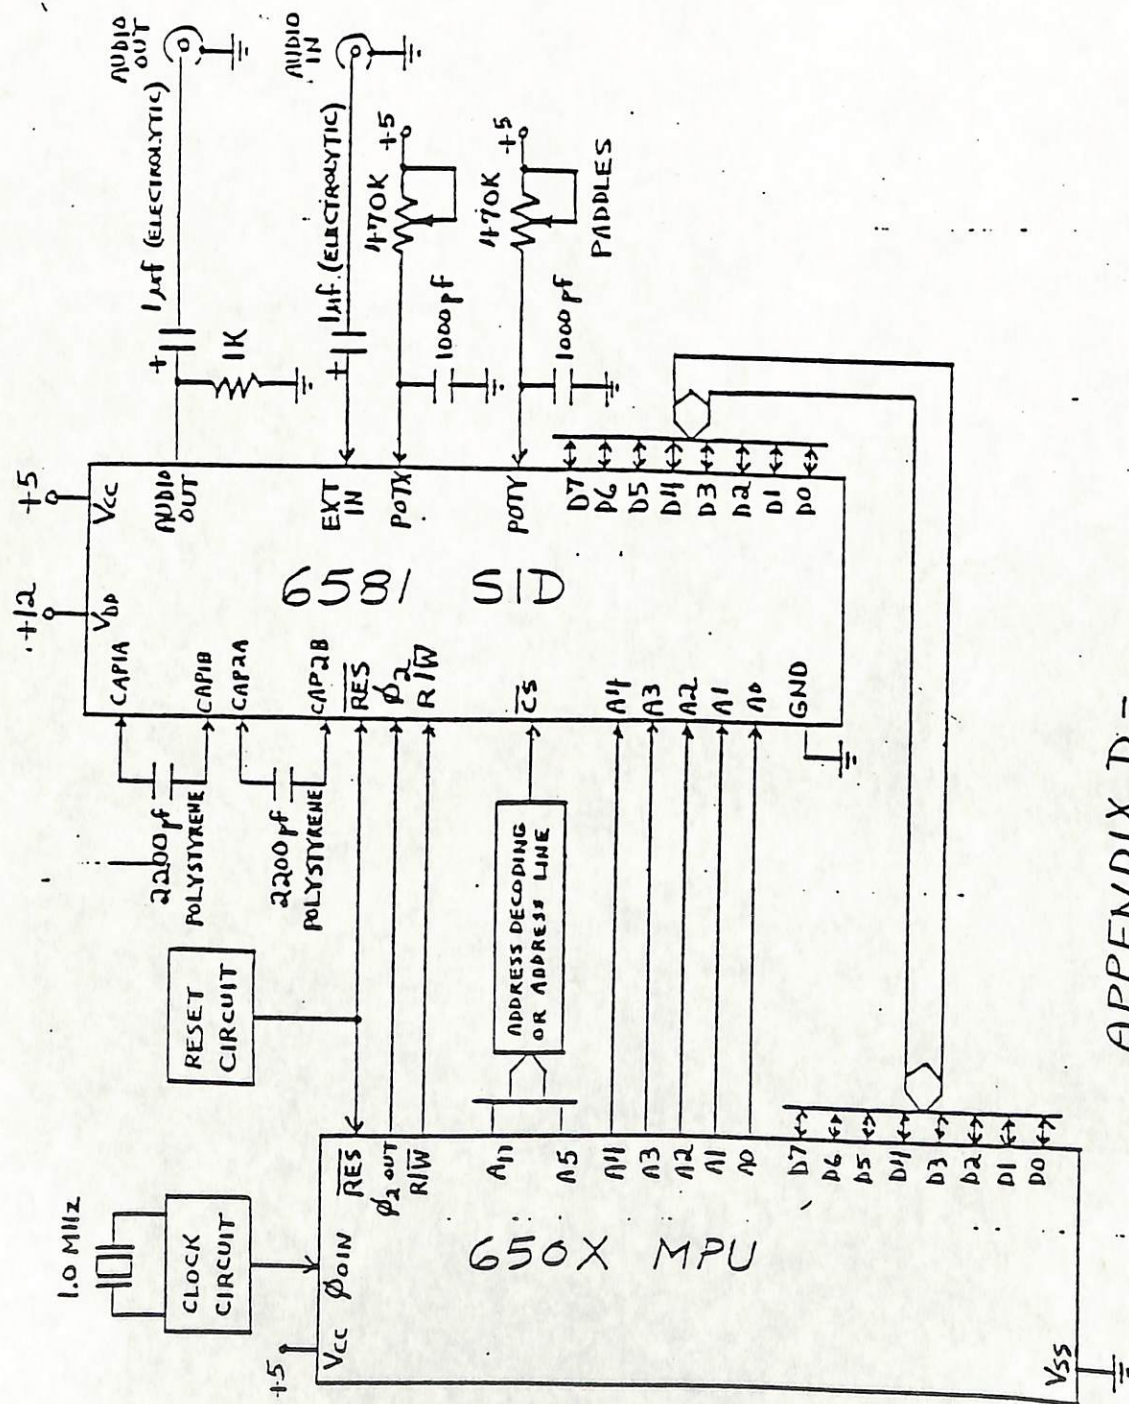

The real power of SID lies in the ability to create original sounds rather than simulations of acoustic instruments. The ADSR is capable of creating envelopes which do not correspond to any "real" instruments. A good example would be the "backwards" envelope. This envelope is characterized by a slow attack and rapid decay which sounds very much like an instrument that has been recorded on tape then played backwards. This envelope is shown below

ATTACK: 10 (SR) 500 mS
 DECAY: 0 6 mS
 SUSTAIN: 15 (SF)
 RELEASE: 3 72 mS

Many unique sounds can be created by applying the amplitude envelope of one instrument to the harmonic structure of another. This produces sounds similar to familiar acoustic instruments, yet notably different. In general, sound is quite subjective and experimentation with various envelope rates and harmonic contents will be necessary in order to achieve the desired sound.

APPENDIX D -
TYPICAL 6581 SID APPLICATION

SECTION III

Commodore 64 Memory Maps

COMMODORE 64 MEMORY MAP

(*=USEFUL MEMORY LOCATION)

HEX	DECIMAL	DESCRIPTION
0000	0	6510 Data-direction register
0001	1	6510 Output register
0002	2	Unused
0003-0004	3-4	Float-Fixed vector
0005-0006	5-6	Fixed-Float vector
0007	7	Search character
0008	8	Scan-quotes flag
0009	9	TAB column save
000A	10	0=LOAD, 1=VERIFY
000B	11	Input buffer pointer/# subscript
000C	12	Default DIM flag
000D	13	Type: FF=string, 00=numeric
000E	14	Type: 00=integer, 00=floating point
000F	15	DATA scan/LIST quote/memory flag
0010	16	Subscript/FNx flag
0011	17	0=INPUT; \$40=GET; \$98=READ
0012	18	ATN sign/Comparison eval flag
0013	19	Current I/O prompt flag
*0014-0015	20-21	Integer value
0016	22	Pointer: temporary string stack
0017-0018	23-24	Last temp string vector
0019-0021	25-28	Stack for temporary strings
0022-0025	34-37	Utility pointer area
0026-002A	38-42	Product area for multiplication
*002B-002C	43-44	Pointer: Start of Basic
*002D-002E	45-46	Pointer: Start of Variables
*002F-0030	47-48	Pointer: Start of Arrays
*0031-0032	49-50	Pointer: End of Arrays
*0033-0034	51-52	Pointer: String storage (moving down)
0035-0036	53-54	Utility string pointer
*0037-0038	55-56	Pointer: Limit of memory
0039-003A	57-58	Current Basic line number
003B-003C	59-60	Previous Basic line number
003D-003E	61-62	Pointer: Basic statement for CONT
003F-0040	63-64	Current DATA line number
0041-0042	65-66	Current DATA address
*0043-0044	67-68	Input vector
0045-0046	69-70	Current variable name
0047-0048	71-72	Current variable address
0049-004A	73-74	Variable pointer for FOR/NEXT
004B-004C	75-76	Y-save; op-save; Basic pointer save
004D	77	Comparison symbol accumulator
004E-0053	78-83	Misc work area, pointers, etc
0054-0056	84-86	Jump vector for functions
0057-0059	87-89	Misc numeric work area
*005A	90	Accum#1: Exponent
*005B-005C	91-92	Accum#1: Mantissa
*005D	93	Accum#1: Sign
005E	94	Series evaluation constant pointer
005F	95	Accum#1 hi-order (overflow)

HEX	DECIMAL	DESCRIPTION
0069-006E	105-110	Accum#2: Exponent, etc.
006F	111	Sign comparison, Acc#1 vs #2
0070	112	Accum#1 lo-order (rounding)
0071-0072	113-114	Cassette buffer length/Series pointer
*0073-008A	115-138	CHRGET subroutine (get BASIC char)
007A-007B	122-123	Basic pointer (within subroutine)
0088-008F	139-143	RND seed value
*0090	144	Status word ST
0091	145	Keyswitch PIA: STOP and RVS flags
0092	146	Timing constant for tape
0093	147	Load=0, Verify=1
0094	148	Serial output: deferred char flag
0095	149	Serial deferred character
0096	150	Tape EOT received
0097	151	Register save
*0098	152	How many open files
*0099	153	Input device (normally 0)
*009A	154	Output (CMD) device, normally 3
009B	155	Tape character parity
009C	156	Byte-received flag
009D	157	Direct=0/0/0 output control
009E	158	Tape Pass 1 error log/char buffer
009F	159	Tape Pass 2 error log connected
*00A0-00A2	160-162	Jiffy Clock (HML)
00A3	163	Serial bit count/EOT flag
00A4	164	Cycle count
00A5	165	Countdown, tape write/bit count
00A6	166	Pointer: tape buffer
00A7	167	Tape Write ldr count/Read pass/inbit
00A8	168	Tape Write new byte/Read error/inbit cnt
00A9	169	Write start bit/Read bit err/stbit
00AA	170	Tape Scan/Cnt/Ld/End/byte assy
00AB	171	Write lead length/Rd checksum/parity
00AC-00AD	172-173	Pointer: tape buffer, scrolling
00AE-00AF	174-175	Tape end addresses/End of program
00B0-00B1	176-177	Tape timing constants
*00B2-00B3	178-179	Pointer: start of tape buffer
00B4	180	Tape timer (1=enable); bit cnt
00B5	181	Tape EOT/RS232 next bit to send
00B6	182	Read character error/outbyte buffer
*00B7	183	# characters in file name
*00B8	184	Current logical file
*00B9	185	Current secondary address
*00BA	186	Current device
*00BB-00BC	187-188	Pointer: to file name
00BD	189	Write shift word/Read input char
00BE	190	# blocks remaining to Write/Read
00BF	191	Serial word buffer
00C0	192	Tape motor interlock
00C1-00C2	193-194	I/O start addresses
00C3-00C4	195-196	Kernel setup pointer
*00C5	197	Current key pressed

HEX	DECIMAL	DESCRIPTION
*0006	198	# chars in keyboard buffer
*0007	199	Screen reverse flag
0008	200	Pointer: End-of-line for input
0009-000A	201-202	Input cursor log (row, column)
*000B	203	Which key: 54 if no key
000C	204	cursor enable (0=flash cursor)
000D	205	Cursor timing countdown
000E	206	Character under cursor
000F	207	Cursor in blink phase
0000	208	Input from screen/from keyboard
*0001-0002	209-210	Pointer to screen line
*0003	211	Position of cursor on above line
0004	212	0=direct cursor, else programmed
*0005	213	Current screen line length
*0006	214	Row where cursor lives
0007	215	Last inkey/checksum/buffer
*0008	216	# of INSERTs outstanding
*0009-00F0	217-240	Screen line link table
00F1	241	Dummy screen link
00F2	242	Screen row marker
*00F3-00F4	243-244	Screen color pointer
00F5-00F6	245-246	Keyboard pointer
00F7-00F8	247-248	RS-232 Rcv pointer
00F9-00FA	249-250	RS-232 Tx pointer
*00FB-00FE	251-254	Operating system free zero page space
00FF	255	Basic storage
0100-010A	256-266	Floating to ASCII work area
010B-013E	267-318	Tape error log
0100-01FF	256-511	Processor stack area
*0200-0258	512-600	Basic input buffer
*0259-0262	601-610	Logical file table
*0263-026C	611-620	Device # table
*026D-0276	621-630	Secondary Address table
*0277-0280	631-640	Keyboard buffer
*0281-0282	641-642	Start of memory for op system
*0283-0284	643-644	Top of memory for op system
0285	645	Serial bus timeout flag
*0286	646	Current color code
0287	647	Color under cursor
*0288	648	Screen memory page
*0289	649	Max size of keyboard buffer
*028A	650	Key repeat (128=repeat all keys)
*028B	651	Repeat speed counter
028C	652	Repeat delay counter
*028D	653	Keyboard Shift/Control flag
028E	654	Last keyboard shift pattern
028F-0290	655-656	Pointer: keyboard decode table
*0291	657	Shift mode switch (0=enabled, 128=locked)
0292	658	Auto scroll down flag (0=on, 128=off)
0293	659	RS232 control register
0294	660	RS232 command register
0295-0296	661-662	Non standard (Bit time/2-100)

HEX	DECIMAL	DESCRIPTION
0297	663	RS-232 status register
0298	664	Number of bits to send
0299-029A	665-666	Baud rate (full) bit time
029B	667	RS232 receive pointer
029C	668	RS232 input pointer
029D	669	RS232 transmit pointer
029E	670	RS232 output pointer

COMMODORE-64 MEMORY MAP CONTROL

The 6510 Microprocessor used in the COMMODORE-64 can address up to 64K Bytes of memory. As the COMMODORE-64 contains 20K Bytes of ROM and 4K Bytes of I/O in addition to the 64K Bytes of RAM, memory management is provided to allow the memory map to be reconfigured for different applications. Five control lines are provided to select various memory maps. Three of the control lines are provided by the I/O port contained in the 6510 processor, while the remaining two lines are supplied by the plug-in cartridge. The two cartridge lines allow the machine to determine what type of cartridge has been inserted.

The three lines on the 6510 (location 0001) are:

LORAM (Bit 0)- Generally this line can be thought of as a control which banks the 8K Byte BASIC ROM out of the microprocessor's address space (however it interacts with the other control lines to produce various memory configurations). Typically, LORAM is programmed high for normal BASIC operation. If LORAM is programmed low, the BASIC ROM will disappear from the memory map and be replaced by 8K Bytes of RAM from \$A000-\$BFFF.

HIRAM (Bit 1)- Generally this line can be thought of as a control which banks the 8K Byte KERNAL ROM out of the microprocessor's address space (however this line also interacts with the other control lines to produce various memory configurations). Typically HIRAM is programmed High for normal BASIC operation. If HIRAM is programmed low, the KERNAL ROM will disappear from the memory map and be replaced by 8K Bytes of RAM from \$C000-\$FFFF.

CHAREN (Bit 2)- This line is used only to bank the 4K Byte Character Generator ROM in or out of the microprocessor's address space. From the microprocessor's point of view, the Character ROM resides in the same address space as the I/O devices (The 4K Byte block from \$0000-\$0FFF). When CHAREN is programmed high, the I/O devices appear in the processor's address space and the Character ROM is not accessible. If CHAREN is programmed low, the Character ROM will appear in the processor's address space and the I/O devices will not be accessible. For normal BASIC operation, CHAREN is programmed high. Realistically, the microprocessor only needs access to the Character ROM if it is necessary to download the character patterns from ROM into RAM. For most applications, the CHAREN bit will be programmed high. It should be noted that in some cases, CHAREN is overridden by the other control lines (CHAREN will have no effect on any memory configuration which deselects the I/O devices).

The two memory control lines provided by the cartridge are:

GAME (Pin 8)- Generally, this line can be thought of as a control which, when low, causes the COMMODORE-64 memory map to "collapse" into the memory map of the COMMODORE ULTIMAX video game (however this line also interacts with the other control lines to produce various memory configurations). On an ULTIMAX game cartridge, this line would be tied low, indicating to the COMMODORE-64 that a GAME cartridge is being used. In other words, the COMMODORE-64 is downward compatible with the ULTIMAX and any cartridge which runs on the ULTIMAX will also plug directly into the COMMODORE-64 and run. When no cartridge is installed, or when a cartridge other than a game is used, this line is held high.

EXROM (Pin 9)- this line is used to bank the 8K Bytes of RAM from \$8000-\$9FFF out of the microprocessor's address space and replace it with up to 8K Bytes of ROM in the plug-in cartridge. This line would be tied low on a BASIC "expansion" cartridge such as "VSP" or "Programmer's Aid" indicating to the COMMODORE-64 that a BASIC expansion cartridge is being used. (In order for an expansion cartridge to "autostart", locations \$8000-\$8001 must contain the Cold Start vector, locations \$8002-\$8003 must contain the Warm Start vector and locations \$8004-\$8008 must contain "CSM80" (in ASCII, with the MSB set on each character in "CSM").) When no cartridge is installed, or when a cartridge other than an expansion cartridge is used, this line is held high.

COMMODORE-64 FUNDAMENTAL MEMORY MAP

E000-FFFF	8K <	KERNAL ROM or RAM
D000-0FFF	4K <	I/O or RAM or CHARACTER ROM
C000-0FFF	4K <	RAM
A000-2FFF	8K <	BASIC ROM or RAM or ROM PLUG-IN
8000-9FFF	8K <	RAM or ROM PLUG-IN
4000-7FFF	16K <	RAM
0000-3FFF	16K <	RAM

I/O BREAKDOWN

0000-03FF	VIC (Video Controller)	1K Bytes
0400-07FF	SIO (Sound Synthesizer)	1K Bytes
0800-0BFF	COLOR RAM	1K Bytes
0C00-0DFF	CIA1 (Keyboard)	256 Bytes
0E00-0FFF	CIA2 (Serial Bus, User Port/RS-232)	256 Bytes
0F00-0FFF	Open I/O slot #1 (CP/M Enable)	256 Bytes
0F00-0FFF	Open I/O slot #2 (Cheap Disk)	256 Bytes

The two open I/O slots are for general purpose user I/O. Special purpose I/O cartridges (such as IEEE) and have been tentatively designated for handling the E-B0 cartridge (CP/M option) and for interfacing to a low-cost high-speed disk system.

5/19/82

COMMODORE-64 MEMORY MAPS

The following tables list the various memory configurations available on the COMMODORE-64, the states of the control lines which select each memory map and the intended use of each map.

(X=don't care, 0=low, 1=high)

This is the default BASIC memory map which provides BASIC 2.0 and 38K contiguous bytes of user RAM.

This map is intended for use with softload languages (including CP/M), providing 52K contiguous bytes of user RAM, I/O devices and I/O driver routines.

This map provides 68K bytes of RAM and I/O devices. The user must write his own I/O driver routines.

This map gives access to all 64K bytes of RAM. The I/O devices must be banked back into the processor's address space for I/O operation.

5/19/82

MEMORY MAPS (Continued)

LORAM=1
HIRAM=1
GAME=0
EXROM=0

8000	8K KERNAL ROM
8000	4K I/O
8000	4K RAM (BUFFER)
8000	8K BASIC ROM
A000	8K ROM CARTRIDGE (BASIC EXP)
8000	16K RAM
4000	16K RAM
0000	

This is the standard configuration for a BASIC system with a BASIC expansion ROM. This map provides 32K contiguous Bytes of user RAM and up to 8K Bytes of BASIC "Enhancement".

LORAM=1
HIRAM=1
GAME=0
EXROM=0

8000	8K KERNAL ROM
8000	4K I/O
8000	4K RAM (BUFFER)
8000	16K ROM CARTRIDGE
8000	16K RAM
4000	16K RAM
0000	

This map provides 32K contiguous Bytes of user RAM and up to 16K Bytes of plug-in ROM for special ROM-based applications which don't require BASIC (word processors, other languages, etc.).

LORAM=0
HIRAM=1
GAME=0
EXROM=0

8000	8K KERNAL ROM
8000	4K I/O
8000	4K RAM (BUFFER)
8000	8K ROM CARTRIDGE
A000	8K RAM
8000	16K RAM
4000	16K RAM
0000	

This map provides 48K contiguous Bytes of user RAM and up to 8K Bytes of plug-in ROM for special ROM-based applications which don't require BASIC.

LORAM=X
HIRAM=X
GAME=0
EXROM=1

8000	8K CARTRIDGE ROM
8000	4K I/O
8000	4K OPEN
8000	8K OPEN
A000	8K CARTRIDGE ROM
8000	16K OPEN
4000	16K OPEN
4000	4K RAM
0000	

This is the ULTIMAX video game memory map. Note that the 2K Byte "expansion RAM" for the ULTIMAX, if required, is accessed out of the COMMODORE-64 and any RAM in the cartridge is ignored.

MISCELLANEOUS INFO

5/19/82

- 1.) The CHAREN control line will bank the Character ROM into the processor's address space in place of the I/O devices with any memory map that includes I/O devices (with the exception of LORAM=1, HIRAM=0, GAME=0 and EXROM=0). Those memory configurations which replace the I/O with RAM (giving access to all 64K Bytes of RAM) are unaffected by the CHAREN line.
- 2.) In any memory map containing ROMs, a WRITE to a ROM location will store data in the RAM which the ROM overlays. That is, writing to a ROM location will, in fact, store data in the "hidden" RAM. This allows, for example, a HI-RES screen to reside underneath a ROM and be changed by the processor without banking the RAM into the processor's address space. Naturally, a READ from a ROM location will return the contents of the ROM and not the "hidden" RAM.
- 3.) The ULTIMAX memory map configuration matches the memory map of the COMMODORE ULTIMAX video game exactly. All open memory blocks in the ULTIMAX are also open on the COMMODORE-64 when this memory map is selected, therefore, any cartridge or device that plugs into the ULTIMAX will also work on the COMMODORE-64. Note that there are only 2K Bytes of RAM in the ULTIMAX and for applications requiring more RAM, the cartridge can contain up to 2K Bytes of expansion RAM. If an ULTIMAX cartridge containing expansion RAM is installed in the COMMODORE-64, the RAM in the cartridge will be ignored and the COMMODORE-64 will use its own internal RAM instead. The COMMODORE-64 Character ROM is not available to ULTIMAX cartridges. As on the ULTIMAX, the 4K Bytes of cartridge ROM from \$F000-\$FFFF are accessible by the VIC video chip and should contain all character and Sprite patterns.
- 4.) All of the memory maps described apply ONLY TO THE MICROPROCESSOR. The VIC video display chip sees a much simpler memory map, regardless of the state of the memory control lines (LORAM, etc.). The VIC can ONLY see RAM or the Character ROM. The VIC chip itself is capable of addressing only 16K Bytes of memory. In order to expand this address space, two I/O Port lines, VA14 and VA15 (location \$0000, bits 0 and 1), are used to form the most significant bits of the VIC address. Essentially these two bits select which of the four 16K banks of memory the VIC can look at. Note that these port bits are INVERTED, that is, setting VA14 and VA15 HIGH will cause the VIC to access the LOW 16K block of memory (from \$0000-\$3FFF). Setting VA14 low and VA15 high will select the second 16K block (\$4000-\$7FFF), etc. The Character ROM is only available to the VIC chip in Bank 0 (\$0000-\$3FFF) and Bank 2 (\$4000-\$7FFF) and appears in the ^{LOW} 4K Bytes of these two banks. In order for the VIC chip to access the Character ROM, bits CB13 and CB12 in the CHARACTER BASE REGISTER of the VIC (Register #18) must be set to a particular state. CB13 should be set low (0) and CB12 should be set high (1). Note that the VIC will not be able to access the 4K Bytes of RAM which the Character ROM displaces. For those applications in which the VIC chip must access a full 16K Bytes of RAM, or for some reason must access RAM in this 4K block of the desired bank, Bank 1 (\$4000-\$7FFF) or Bank 3 (\$8000-\$FFFF) should be used, as the Character ROM is disabled in these banks.

The VSP package will automatically handle the bank switching necessary to plot into the RAM underneath the BASIC and VSP ROMs.

5.2 Explanation of certain cartridge lines:

Pin 6, CLOCK- This line is the 8.18 MHz video dot clock from which all system timing is derived.

Pin 7, I/O #1- This is a negative active chip select for the block of memory from \$0E00-\$0EFF (256 Bytes).

Pin 10, I/O #2- This is a negative active chip select for the block of memory from \$0F00-\$0FFF (256 Bytes).

Pin 11, ROML- This is a negative active chip select for the block of memory from \$8000-\$8FFF (8K Bytes). This is true for all COMMODORE-64 memory maps, including ULTIMAX. Any cartridge ROMs which are to appear in the \$8000 block (VSP, etc.) should have their CS pin connected to this line.

Pin 12, BA- This is the BUS AVAILABLE signal from the VIC chip. This line will go low three cycles before the VIC takes over the system busses and remain low until VIC is finished fetching display information.

Pin 13, DMA- This line allows external devices, such as the Z-80 microprocessor cartridge, to take control of the system busses. When pulled low, the address bus, data bus and R/W line of the 6510 processor are Tri-stated. This line should only be pulled low when the C2 clock is low. In addition, the VIC chip will continue to perform display DMA, therefore the external device must conform to the VIC timing. This line is pulled-up on the COMMODORE-64.

Pin 8, ROMH- This is a negative active chip select for the block of memory from \$8000-\$8FFF (8K Bytes) for all COMMODORE-64 memory maps except for the ULTIMAX map. For the ULTIMAX map, this line is a negative active chip select for the block of memory from \$E000-\$EFFF (8K Bytes). Any cartridge ROMs which are to appear in the \$8000 block (in place of BASIC) should have their CS pin tied to this line. Any ULTIMAX game ROM which is to appear in the \$E000 block should have the CS pin tied to this line.

SOFTWARE APPLICATION

NOTE 1001

Authors: Joe McEnerney, Eric Cotton, and Bill Hindorff

Subject: Sprite Movement

Television Standard: This Application Note explains sprite movement for both PAL and NTSC versions of the VIC II chip.

I. X MOVEMENT and X COMPARE

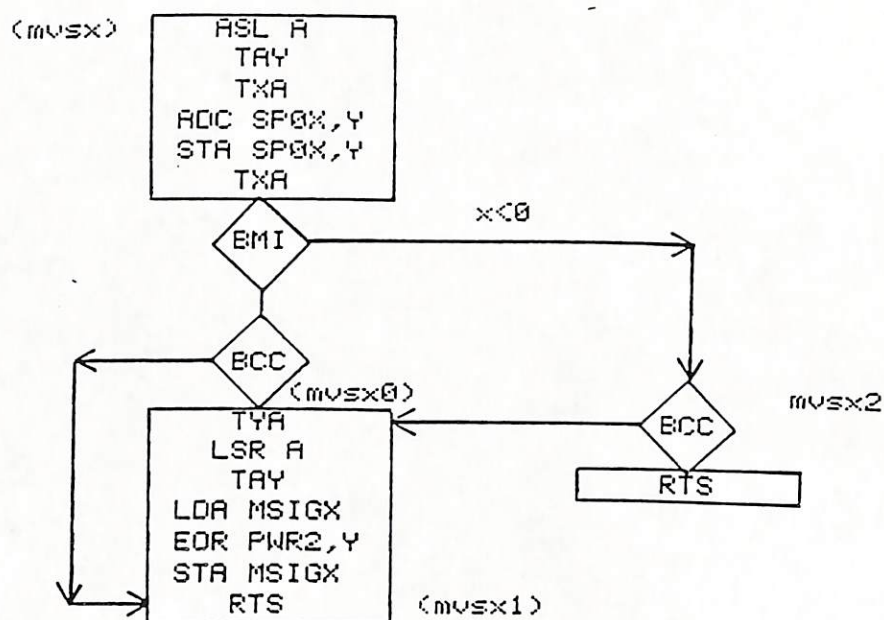

A. X MOVEMENT

1. Abstract: There are \$200 possible x positions for a sprite on a NTSC version of the VIC II chip ($\$0 \leq x \leq \$1FF$), while on the PAL version there are \$1F8 ($\$0 \leq x \leq \$1F7$). Because positions \$1F8 through \$1FF do not exist on the PAL version, two separate x movement subroutines are presented below. The first, MVSX, is for sprites expanded or unexpanded in x on NTSC systems, and/or for sprites unexpanded in x on PAL systems. The second, UNIMVX, is a universal routine: It works for all sprites, expanded or unexpanded in x, on both television standards. However, because it is slower and uses more memory than MVSX, the programmer should limit its use to those occasions when his program requires movement of sprites expanded in x on PAL systems across the range $\$1F8 \leq x \leq \$1FF$.

Immediately before calling either of the subroutines the accumulator must be loaded with the sprite number (0 through 7) and the x register with the two's complement offset. The user should note the additional requirements of UNIMVX. In both, however, it does not matter whether the sprite is expanded or unexpanded in y.

2. Exposition - MVSX: The following deals with x movement of sprites expanded or unexpanded in x on NTSC television systems, and/or sprites unexpanded in x on PAL systems.

c. Memory/Register requirements: This routine requires 38 (\$26) bytes of memory, including 8 bytes for the table of the powers-of-two (PWR2). It uses the accumulator and the x and y registers.

d. Worst case execution time is 55 (\$37) cycles (53.90 micro-seconds).

2. Exposition - UNIMVX: This section deals with x movement of sprites expanded or unexpanded in x on NTSC or PAL television systems. UNIMVX operates the same as MVSX insofar as the accumulator must first be loaded with the sprite number (0 through 7) and the y register with the two's complement offset. However, because this is a universal (NTSC or PAL) x movement routine, there must also be a routine to check on which television system the routine is being used and then communicate this information to the UNIMVX subroutine. Because the NTSC system is based on 262 raster lines per screen while the PAL system is based on 312, the presence of a raster 263 (or greater) would imply the PAL system. Thus we include TVSTD which checks to see if a raster line greater than 264 is scanned. (Raster 264 is used as the compare value instead of 263 to insure that the correct system is chosen.) If the raster passes 264, then the PAL system is in use; otherwise, the NTSC system is. To communicate its finding to UNIMVX, TVSTD stores the high and low bytes of the first illegal x position for the system in the variables MOOH and MOOL, respectively: \$1F8 for the PAL and \$200 for the NTSC.

Following UNIMVX there are two additional subroutines, VTAMX and ATVMX. VTAMX need only be executed once, sometime before UNIMVX is called the first time. Its purpose is to copy the x position MSB's from MSIGX (\$0010) to individual locations in RAM (starting with SMSB). The second routine, ATVMX, does the opposite: It copies the RAM MSB's back into MSIGX. It should be executed after all of the sprites' x positions have been updated.

In summary, the user must follow this procedure: Execute TVSTD and VTAMX once each at the beginning of the program. Then, every time a sprite is to be moved in the x direction: 1) Load the accumulator with the sprite number. 2) Load the x register with the two's complement offset. 3) Execute UNIMVX. 4) Loop back to step 2 if more sprites are to be updated. 5) Execute VTAMX. (See Section III. B. of

this Application Note for an example using UNIMVX.)

B. X COMPARE

1. Abstract: This routine checks to see if any bit of a given sprite is in the viewable region of the screen. The accumulator must be loaded with the sprite number (0 through 7) prior to use. At RTS time the carry flag indicates the answer. If carry=1, then the sprite is on the screen; if carry=0, then the sprite is off screen.

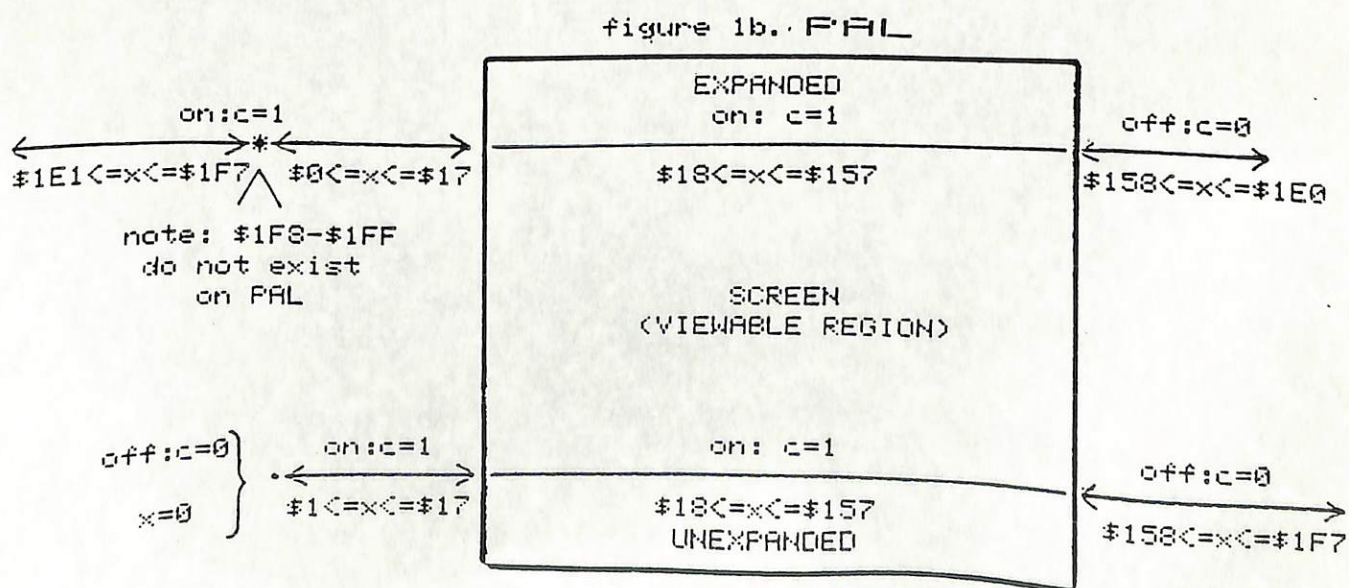

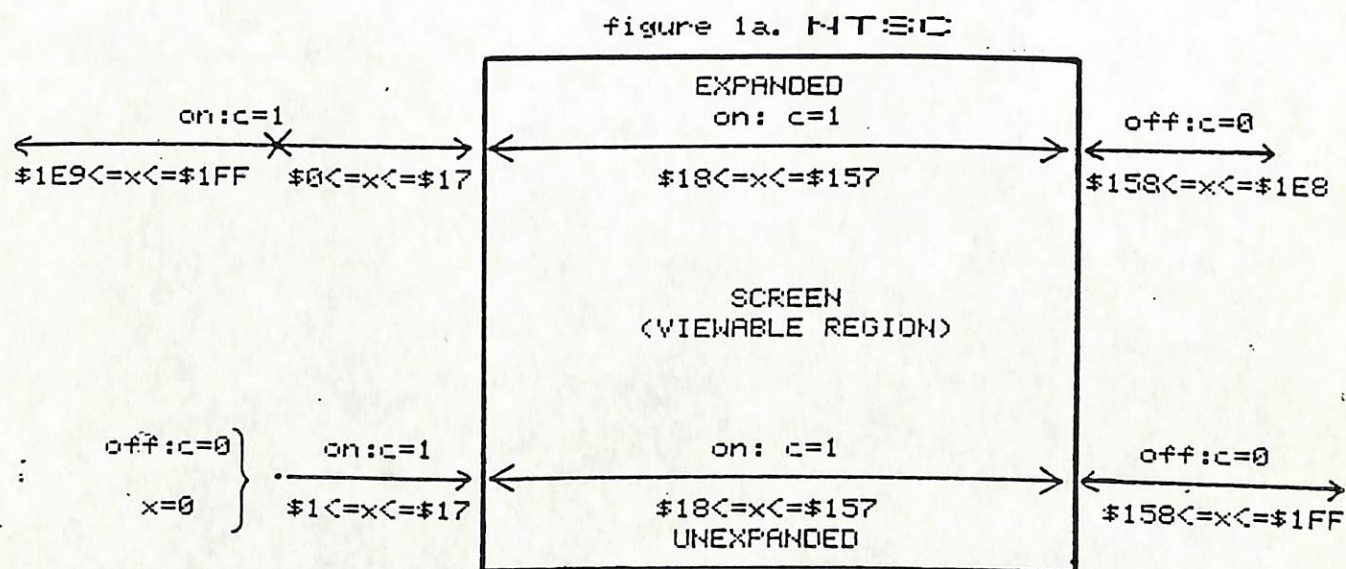

2. Exposition: The following exposition deals with x 40 column window compare of sprites unexpanded in x on NTSC or PAL television systems. Section I. B. 3. explains how this routine may be modified for sprites expanded in x.

a. Flow chart

b. Diagrams: The following diagrams illustrate the on and off screen areas for a sprite. Figure 1a is for NTSC systems and figure 1b is for PAL. In each, the top half shows the case for sprites expanded in x, while the bottom shows the unexpanded case. If the SPONX (or SONXX for exp. sprites) is called with the sprite in the on-screen area, carry would be set upon returning. If called with the sprite is entirely in the off-screen area, carry would be clear.

4. NOTES:

a. The changes below modify SPONX to set carry only if the entire sprite is on screen but clear carry otherwise. (Line numbers refer to source listing.)

8/25/82

Commodore

page 9

- 1) Sprites unexpanded in x:
 - a) change line 1160 from BEQ SPONX0 to CMP #18
 - b) delete line1170
 - c) change line 1200 from LDA #57 to LDA #40
- 2) Sprites expanded in x:
 - a) change line 1160 from BEQ SPONX0 to CMP #18
 - b) delete line1170
 - c) change line 1200 from LDA #57 to LDA #28

b. Sometimes it is more useful to know if any part of a sprite is entirely on screen but not at an edge, such as the case when a sprite is to be kept confined to the screen. The changes below modify SPONX in this regard: carry is cleared if the sprite is all or partially offscreen or if it is at either the left or right edge. Care should be taken when the movement offset is greater than 1. The sprite could jump over an edge and flag the user only after the sprite is all or partially off screen. If the offset is 1, however, this will not happen. (Again, line numbers refer to the source listing.)

- 1) Sprites unexpanded in x:
 - a) change line 1160 from BEQ SPONX0 to CMP #19
 - b) delete line1170
 - c) change line 1200 from LDA #57 to LDA #3F
- 2) Sprites expanded in x:
 - a) change line 1160 from BEQ SPONX0 to CMP #19
 - b) delete line1170
 - c) change line 1200 from LDA #57 to LDA #27

II. Y MOVEMENT and Y COMPARE

A. Y MOVEMENT

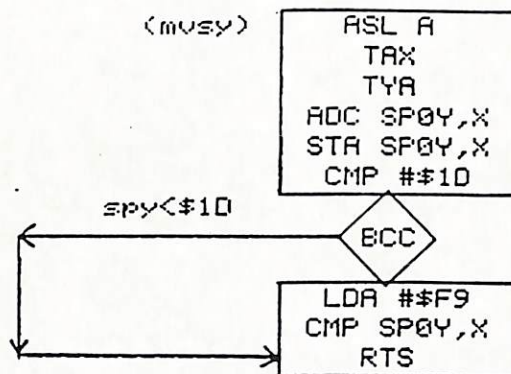

together in one routine

B. Y COMPARE

1. Abstract: This routine moves a given sprite in the y axis by an offset specified by a two's complement amount loaded into the Y register prior to calling this routine. The sprite number (0 through 7) must be loaded into the accumulator before the routine is executed. At RTS time the carry flag reflects the status of the sprite with respect to the exterior region. Thus, if carry=1 then the sprite is on the screen; if carry=0 then the sprite is off screen. The subroutine below works on both NTSC and PAL television systems. Only slight modification is necessary to make the routine work with sprites expanded in Y.

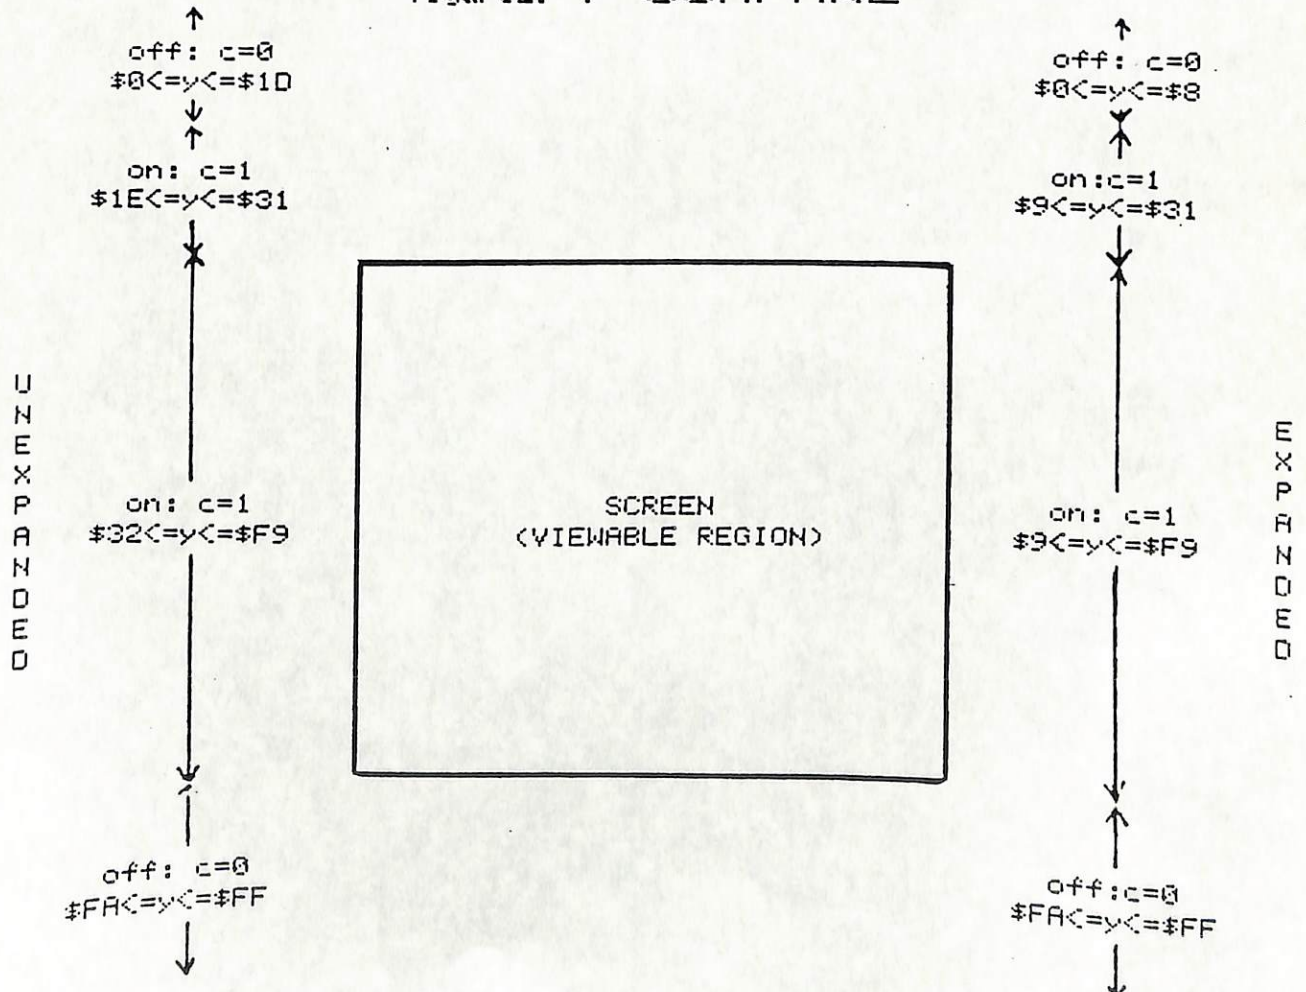

2. Exposition:

a. Flow chart:

b. Diagram: Figure 2 below shows the ranges of sprite y positions for which the sprite is on-screen (carry=1) or off-screen (carry=0).

1010 data 29,144,5,169,249,221,1,208,96

```

d. Memory/Register requirements: This routine requires 19 (\$13) bytes of memory as well as the accumulator and the x and y registers.

e. Worst case execution time is 31 (\$1F) machine cycles (30.38 micro-seconds).

f. Limitations: This routine assumes that the VIC II chip is in 25 row mode and that the sprite in question is unexpanded in y (unless the routine has been changed as specified in section g below).

g. If this routine is to be used with sprites expanded in y, then change line 1120 of the editor listing from `CMP #$10` to `CMP #$03`. This change is applicable when using y-expanded sprites on either NTSC or PAL television systems.

3. NOTES:

a. The changes below modify MVSX to set carry only if the ~~entire~~ sprite is on screen, but clear it otherwise. (Line numbers refer to the source listing.)

- 1) Sprites unexpanded in y:
 - a) change line 1120 from CMP #\$1D to CMP #\$32
 - c) change line 1140 from LDA #\$F9 to LDA #\$E5

- 1) Sprites expanded in y:
 - a) change line 1120 from CMP #\$1D to CMP #\$32
 - c) change line 1140 from LDA #\$F9 to LDA #\$D0

b. Sometimes it is more useful to know if any part of a sprite is entirely on screen but not at an edge, such as the case when a sprite is to be kept confined to the screen. The changes below modify MVSX in this regard: carry is cleared if the sprite is all or partially offscreen ~~or~~ if it is at either the top or bottom edge. Care should be taken if the movement offset is greater than 1. The sprite could jump over an edge and flag the user only after the sprite is all or partially off screen. If the offset is 1, however, this will not happen. (Again, line numbers refer to the source listing.)

- 1) Sprites unexpanded in y:
 - a) change line 1120 from CMP #\$1D to CMP #\$33
 - c) change line 1140 from LDA #\$F9 to LDA #\$E4

- 1) Sprites expanded in y:
 - a) change line 1120 from CMP #\$1D to CMP #\$34
 - c) change line 1140 from LDA #\$F9 to LDA #\$Cf

III. EXAMPLES

A. EXAMPLE 1

The example below uses all three main subroutines presented in this Application Note. Its purpose is to demonstrate the use of the routines in an actual program. When executed, this program will bounce an unexpanded sprite around the screen on either television system. The MVSX and MVSX subroutines move the sprite until it is entirely off the screen (as indicated by SPONX or MVSX). If, after moving the sprite in the x direction, the x compare indicates that the sprite has gone off screen, then the x direction is reversed. The same is true for y movement.

By modifying the subroutines as explained elsewhere in this note, the example can be made to work with an expanded sprite. (Remove lines 1250 and 1260 of the example if an expanded sprite is to be used).

NOTE:

The subroutine WAIT has been added to slow down the example and thus better enable the programmer to follow its execution. This delay loop lasts for about 20662 machine cycles, equivalent to about 20.25 milliseconds.

      B. EXAMPLE 2

```

This example demonstrates the use of UNIMVX and its auxiliary subroutines. When executed, it will display a solid x-expanded sprite on the screen. In the upper-right corner of the screen is shown the x position of the sprite in hexadecimal notation. By pressing the cursor-right key, the user can move the sprite right across (and around) the screen. Because the universal x-movement routine is used, this example checks for the television standard used. Note that on a PAL television the sprite moves from \$1F7 to 0.

NOTES:

- 1) This example steps on zero page and contains the BRK command. For these reasons it should be run from VICMON (with an alternate zero page enabled).
- 2) The user is advised to experiment with the routine by changing the two's complement offset in line 1590 of the source listing to different values.

SOFTWARE APPLICATION NOTE 1002

Author : Joe McEnerney & Bill Hindorff

Subject : Sprite/Character Utility Operators

Television Standard : NTSC or PAL

Abstract : These routines allow various manipulations of RAM which contains a sprite or a character. Prior to being called, source pointers (SRC1 and SRC2) and a destination pointer (DST) must be set up. Each routine has three entry points...the first is for characters, the second for sprites, and the last for a user-defined block of RAM. The last entry point requires the user to initialize the y register to the total number of bytes to operate on minus one. The routines include: transferring a block of memory, logically ANDing two blocks of memory together and storing the result in a third block, logically ORing two blocks of memory, and logically EORing two blocks of memory. A second set of routines logically ANDs a block of memory with a single byte mask, logically ORs a block of memory with a mask, and logically EORs a block of memory with a mask.

Exposition :

b) Program listing as assembled at \$C100.

```

b) Memory/Register requirements: These routines require 160 bytes of memory and 7 bytes of zero page RAM. They use the accumulator and the x and y registers.

c) Worst case execution time is 1458 cycles (or 1428.84 usecs on a 1.02 MHz system).

d) Prior to using this subroutine the appropriate pointers must be initialized for the subroutine being used. Refer to the subroutine's comments to find out what variables must be pre-set.

e) Example: The following program initializes the three sprite pointers, ORs two sprite patterns together, and places the result in memory starting at the destination pointer.

```
1000 ORTWO
1010     LDA #07F8
1020     LDX #00
1030     JSR SPPA      ;SET SOURCE 1 ADDRESS
1040     LDA #07F9
1050     LDX #02
1060     JSR SPPA      ;SET SOURCE 2 ADDRESS
1070     LDA #07FA
1080     LDX #04
1090     JSR SPPA      ;SET DESTINATION ADDRESS
1100     JSR SORS      ;OR THE TWO PATTERNS AND STORE
1200     RTS
```

SOFTWARE APPLICATION
NOTE 1223

Author : Bill Rindorf

Subject : Sprite pattern mirroring and shifting.

Television Standard : NTSC or PAL

Abstract : These routines take a user defined sprite in RAM and reflect it about its central y-axis, reflect it about its central x-axis, shift/rotate left, and shift/rotate up. Prior to being called, a pointer to the starting address of the sprite data (spr) must be initialized. In the case of shifting or rotating, the x register must also be set with the number of bits to shift.

Exposition :

a) Diagrams: The two patterns below illustrate a sprite before being flipped about the y-axis and after being flipped.

YFLIP

These views show a sprite being rotated left 1 bit.

SROL

This illustration shows a before and after shot of a sprite being mirrored about the x-axis.

FLIPX

The patterns below represent a sprite which has been shifted up 1 bit (x register = \$01).

SFTUP

A before and after view of a sprite being shifted left 1 bit (x register = \$01).

SASL

Sprite before being rotated up 1 bit, and after being rotated.

b) Program listing as assembled at \$C100.

1) Assembly:

c) Memory/Register requirements: This routine requires 321 (#141) bytes of memory. It uses the accumulator, X, and Y registers and 7 bytes of storage.

d) Worst case execution time is $1082 \times Z + 29$ cycles for the SROUP routine. Where Z is equal to the number of times the sprite is rotated up.

e) Limitations: To mirror a multi-color sprite about the y-axis, the yflip routine is called then multi-color location 37 (#25) and the sprite color location 39 to 46 (#27 to #2e) are interchanged. Note that this will only work for one sprite unless all sprites have the same coloring. Also, the sprite pattern must be in RAM.

f) Prior to using these subroutines a pointer to the beginning of the sprite (called spr) must be set-up (see the SPPA routine of Appnote #1002). The shift routines also require that the X register be conditioned with the number of bits to shift.

3) Example: This example copies a sprite pattern to RAM then flips it about the x-axis. After the pattern is flipped, it is shifted up to its original location within the sprite matrix.

SOFTWARE APPLICATION
NOTE 1004

AUTHORS : Andy Finkel and Joe McEnerney
SUBJECT : Sprite Collision Detection
TELEVISION : NTSC or PAL

ABSTRACT

The detection of collisions is often an important part of computer and video games. The 6566/6567 system supports two types of collisions: sprite to sprite collisions and sprite to screen data collisions. In general, a collision is defined as the instance when non-transparent sprite data coincides with either non-transparent data on another sprite or non-transparent data on the screen.

A. SPRITE TO SPRITE COLLISIONS

ABSTRACT

This routine will interpret the sprite collision and sprite position data provided by the VIC-II 6566/6567 chip to determine which sprites are actually in collision. The collision detection register on the 6566/6567 chip is used to determine which sprites COULD be involved in a collision at the time this routine is called. Then the X and Y positions of the sprites and the size of the player sprite are used to decide which sprites are actually involved in the collision.

9/15/82

Commodore

page 1

EXPOSITION

The routine is called with one sprite defined as the PLAYER sprite. All collisions are reported in reference to the player. To increase the accuracy of collision detection, the SIZE of the player (the highest X and Y values that are non-transparent in this sprite) is also passed to the collision detection routine.

The detection routine returns the number of collisions that the player is involved in. If the player is involved in NO collisions a zero will be returned, EVEN IF THERE ARE OTHER COLLISIONS ON THE SCREEN THAT THE PLAYER IS NOT INVOLVED IN. The sprite numbers of the other sprites involved in the collision are returned in the 7 byte RESULTS array. Up to 7 collisions are possible.

This routine should be called at the end of the frame (during vertical blanking). If a raster driven interrupt routine is being used, this routine can easily become part of that routine.

MEMORY/REGISTER REQUIREMENTS

This routine uses the accumulator, the .X and the .Y registers, and 2 bytes on the stack. 17 locations on zero page are needed. The routine takes 136 bytes of memory.

WORST CASE EXECUTION TIME

1055 cycles (1034 microseconds on a 1.02 Mhz system)

EXAMPLE:

```

E1   LDA #23           ;SET PLAYER SIZE
      STA PXMAY
      LDA #21
      STA PLYMAX
;
      LDX #0           ;CHECK ON SPRITE #0 COLLISIONS
      JSR BANG
;
      LDA COUNT        ;ANY COLLISIONS ?
      BEQ SKIP         ;NO
;
AGAIN LDX COUNT        ;BLOW UP EVERYONE IN COLLISION
      LDA RESULT,X     ;GET NUMBER OF SPRITE TO EXPLODE
      JSR EXPLOD       ;(DO EXPLOSION ROUTINE)
      DEC COUNT
      BPL AGAIN
;
      LDA #0           ;NOW BLOW PLAYER UP
      JSR EXPLOD
      RTS

```

NOTE: Remember that sprite to sprite collisions can take place even off screen.

ADDITION: Center Collision Detection

ABSTRACT:

The following modification of the collision detection routine gives the ability to use the center of a sprite to check collisions rather than the top left corner. Instead of the valid collision area centering on the upper left corner of the player sprite, the valid collision area will be centered on a point within the sprite.

EXPOSITION

The modification to the routine is confined to two areas: that is, the addition of 2 constants describing the center location of a sprite and modification of the sprite location subroutine to use this center.

MEMORY/REGISTER REQUIREMENTS

This routine uses the accumulator, the .X and the .Y registers, and 2 bytes on the stack. The routine requires 12 bytes of zero page RAM storage. The program takes 140 bytes of memory.

WORST CASE EXECUTION TIME

1245 cycles (1220 microseconds on a 1.02 Mhz system)

LIMITS

It is possible for this routine to report false collisions in the case of two or more sprites having some part in the area defined

9/15/82

Commodore

Page 11

APP NOTE 1004

COLLISION DETECTION

by the player size. The following picture makes this clear:

7/15/82

Commodore

page 12

```

                00000000000000
                B                B
                0                0
AAAAAAAAA0AAAAA    B
A        00000000000000
A                A
A        P P P P P P P P P P
A        P  A      P
A        P  A      P
AAAAAAAAPAAAA    P
                P
                P P P P P P P P P P

```

As you can see, the player is colliding with sprite A only. But sprite A is colliding both with the player and with sprite B. When the collision detection routine is called, it will report that the player is in collision with BOTH A and B, since each is involved in a collision at the time, and both are within the size of the player sprite.

B. SPRITE TO BACKGROUND COLLISION DETECTION

ABSTRACT

This routine will translate the (X,Y) coordinates of the position of a sprite to background collision into a row/column address on the video matrix. If the sprite center is off screen, an error is flagged. The coordinates of the sprite are in the normal range of $0 \leq X \leq 511$ and $0 \leq Y \leq 255$. The row/column address is in the range $0 \leq X \leq 39$ and $0 \leq Y \leq 24$.

EXPOSITION

Often in a program it is necessary to know not only that a collision between a sprite and background data took place, but where it took place as well. If only the fact that a collision took place

is needed by a program, this routine is unnecessary, as the sprite background collision register may be used alone in that case. However, if the location of the collision on the screen is needed (to see exactly what the sprite hit, for example), the following routine can be used.

This routine is one approach to the problem. There are some rather important limits to this routine, however. See the LIMITS section (below) for more information.

MEMORY/REGISTER REQUIREMENTS

This routine uses the accumulator, the .X and the .Y registers. The routine requires 3 bytes of zero page RAM storage. The routine takes up 78 bytes of memory.

WORST CASE EXECUTION TIME

9/15/82

Commander

Page 17

100 cycles (90 microseconds in a 1.02 Mhz system)

LIMITS

As mentioned in the EXPOSITION section, there are definite limits on this routine. The problem is that a sprite takes up roughly 9 character positions on the screen when unexpanded, and 10 when expanded. The sprite to background collision could be anywhere in that 9 (or 10) character area that the sprite is covering. It is difficult to tell where the collision actually took place.

There are several solutions to the problem, none completely satisfactory. The data making up the 9 (or 10) characters could be compared with the data making up the sprite. However, this approach can lead to serious processing time, especially if the sprite does not happen to be on a character boundary.

One possible solution is to allow only certain characters could be allowed to cause a collision. Each of the 9 (or 10) characters possible must be checked on the screen for this to work. If the size of the sprite is precisely known, the number of characters to be checked might be reduced.

Another approach (which will be used in the following example) defines a 'critical area', a one character center of the sprite which we use as the key spot to inspect on the video matrix. This approach works best when the background objects on the screen are large.

There are many other approaches. The success of any will depend on the logic of rest of the program.

IMPORTANT NOTE: If multi-color characters are used, the problem can be reduced by making non-critical objects (objects which should not cause collisions) in 01 multi-color. The 6566/6567 chip will not report a collision between a sprite and an object of this color (bit pattern).

EXAMPLE 1

Sometimes more information than the screen matrix address of the sprite is needed. The following example uses the row and column returned by the sprite to background collision detection routine and sets the character under the top left corner of the sprite.

MEMORY/REGISTER REQUIREMENTS

This routine uses the accumulator, the .X index register, the .Y index register, and 2 bytes on the stack. 5 bytes of storage on zero page are required. The routine takes up 150 bytes of memory.

WORST CASE EXECUTION TIME

150 cycles (147 microseconds on a 1.02 Mhz system)

EXAMPLE 2

Here is another example which puts the collision detection routines together with the move routines and the clock routines. This example gives an idea of how a total program can go together.

Three sprites are displayed. On the top line, left to right, are the coordinates (in hex) of sprite 2 (the red sprite), sprite 1 (the white sprite), and sprite 0 (the black sprite). Sprite to sprite collisions are displayed on the left half of the second line. The number(s) of any sprite(s) colliding with the player sprite are shown. On the right side of the second line the row and column screen matrix address (in hex) of the sprite is displayed during a sprite to background collision.

SOFTWARE APPLICATION

NOTE 1005.a

Authors = Eric Cotton and Andy Finkel

Subject = Raster Scan - Multiple Sprite Interrupt Routine

Television Standard = NTSC and PAL

I. ABSTRACT: The purpose of this application note is to supply a method for displaying up to 16 sprites on the screen simultaneously. When a program uses one to eight sprites at a time, the VIC II sprite registers are usually updated once per frame while the raster is not scanning the visible viewing area. If, however, immediately after a sprite is drawn on the screen we change its position to a location following the raster, the sprite will be drawn once again at the new location. For example, suppose we position a sprite on the screen at x=200, y=70. If, after the raster moves past the bottom of the sprite, we change the y coordinate to 150 the raster will draw the sprite again at x=200, y=150. For a brief instant the sprite will be displayed on two parts of the screen simultaneously. By applying this technique to the other sprites we find that we can display 16 sprites (or more, if we repeat the process) at a time.

II - EXPOSITION: The IRQ service routine (IRQSVC)
(c) 1982 Commodore

Page 1

presented in this application note allows the user to display 16 sprites on the screen at a time (under program control). Instead of writing sprite information directly to the VIC, the user should write to two pseudo VIC chips located on zero page. Each pseudo chip controls eight sprites (set1 and set2). Set 1 sprites should be limited to y positions in the top half of the screen and set 2 sprites should be limited to y positions in the bottom half. Each set is alternately transferred to the real VIC chip by the IRQ routine.

Interrupts are generated when the raster is at the middle of the screen (raster=\$98) and when it is just past the visible viewing area (raster=\$FA). The first transfers data from the bottom eight sprites (set 2) to the VIC chip, while the second transfers the data from the top eight (set 1).

Included is a set-up routine which: (1) disables interrupts from the 6526 CIA, (2) loads the IRQ vector at \$0314-\$0315 with the address of the new routine, (3) disables all VIC II interrupts except for raster-compare, and (4) sets the first interrupt for raster line \$FA.

A. Pseudo VIC Chip Register Map: The following map shows the address, name, set, and corresponding VIC II chip location (where applicable) for each pseudo register. All numbers are in hexadecimal.

```

C. Memory/Register Requirements: The set up routine (SETUP) requires 32 (\$20) bytes of memory (excluding the endless loop on line 1830) and uses the accumulator. The interrupt service routine, IRQSVC, requires 101 (\$65) bytes and uses the accumulator, and the x and y registers. Also, 75 (\$4b) bytes of zero page must be reserved for variables.

D. Worst case execution time is 40 cycles (39.08 micro-seconds at 1.02 MHz) for SETUP (excluding line 1830) and 530 cycles (517.81 micro-seconds) for IRQSVC.

E. User Notes:

1. During each interrupt the sprite-to-sprite and sprite-to-data collision registers are stored for use in a collision routine.

2. Whenever any or all of a sprite from one set is

positioned in the part of the screen reserved for the other, problems may develop. At best only flickering will occur, but at worst sprites may be split or color and sprite data may change in the middle. Sprites expanded in y have limited mobility because of a greater likelihood of crossing boundaries.

3. IRQSVC does not push any of the registers onto the stack upon interrupt. If executed on a Commodore 64, this is done by the KERNAL (assuming lines 1710-1740 are left intact). The MAX Machine (or a Commodore 64 which emulates a MAX), however, does not have a KERNAL. Therefore, the contents of locations \$FFFE and \$FFFF should contain the address of IRQSVC (low byte, high byte order). Further, at the start of the IRQ routine should be the following code to push the registers onto the stack:

PHA

TXA

PHA

TYA

PHA

F. Example: The following example enables sixteen sprites and moves them around the screen in the x direction. Sample sprite data has been provided on the development disk under the name 'numbers.bin'. The data should be loaded from VICMON (XVM4.8).

SOFTWARE APPLICATION NOTE 1005B

AUTHOR : Andy Finkel
SUBJECT : Multi-sprite processor
TV STANDARD : NTSC or PAL

ABSTRACT

This applications note describes a method for displaying up to 32 sprites on the screen at the same time through software interrupt control. Four 'shadow' VIC-II chips are created and maintained by the multi-sprite routine. The shadow registers on the chips are mapped into the actual VIC-II hardware sprite registers under interrupt control.

EXPOSITION

The multi-sprite routine is an IRQ driven interrupt routine which can maintain up to 4 shadow VIC-II chips. Each of the shadow chips is assigned an area of the screen by the programmer. Each chip has the use of the 8 sprites in its section of screen, as well as control of the background color. Any sprites used by a shadow chip must stay in the area controlled by that shadow chip. If this rule is violated, it is possible that the sprite will not be displayed. The following charts shows the area of control for each of the 4 shadow VIC-II chips.

CHIP	RASTER LINE OF INTERRUPT (CEN)	AREA OF CONTROL
0	48	49-100
1	100	101-160
2	160	161-199
3	199	200-48 (wraps around to the top of the screen)

Note that the bottom of the area of control of each chip is defined by the start of the area of control of the next chip. i.e. the bottom of chip 1's area is defined as the beginning of chip 2's area. The areas of control can be changed dynamically, but should be at least 21 raster lines apart when using unexpanded (in Y) sprites, or 42 raster lines apart when using Y expanded sprites.

There are four main control locations, one for each of the shadow chips, called CEN (Chip ENable) in the routine. If one of the CEN locations contains a 0, that chip is DISABLED. Otherwise, each is to be set to one before the desired raster line of the area of control for the chip. The background color is changed one raster line later. The new sprites are activated several raster lines after that.

LIMITS

Care must be taken that a sprite maintained by one pseudo VIC chip does not wander into the area under the control of another VIC chip. If this happens, one of the sprites will not be displayed.

Generally, the sprite that belongs in that area will have priority.

If it is desired to have a sprite that can go anywhere on the screen, the easiest method is to duplicate the parameters (position, color, and pointer) in each of the VIC chips. That way, the appropriate VIC chip will display the sprite.

SOFTWARE APPLICATION

NOTE 2001

Authors: Joe McEnerney and Eric Cotton

Subject: Addressing the Video and Color Matrices

Television Standard: NTSC or PAL

I. Abstract: The purpose of this application note is to supply a method of addressing the video and color matrices by specifying row and column numbers for the matrix element of concern. This will be achieved using the indirect indexed addressing mode of the 650x microprocessor and an auxiliary table.

II. EXPOSITION: In order to address an arbitrary element of any matrix of bytes stored in memory the user must have a base address B, a row number R, a column number C, the number of rows NR, and the number of columns NC. The number R must satisfy the inequality $0 \leq R \leq NR-1$ and C must satisfy $0 \leq C \leq NC-1$. The address, AE, of an arbitrary element can be found by performing the calculation

$$AE = R*NC+C+B.$$

This formula requires one multiply and two additions to find A. This is a rather high price to pay in execution time and memory. To solve these problems one can store the precalculated values $R*NC+B$, $0 \leq R \leq NR-1$ in a table and use C as an index value. These table entries are, in fact, the addresses of the first element of each row of the matrix. Now, in our application of this principle, the matrix has 25 rows ($NR=25$) and 40 columns ($NC=40$). The base address is chosen by the user by selecting the high address bits VM13, ..., VM10 in register 24 (\$18) of the 6566/6567 VIC II chip. By pre-calculating the table of addresses

$$40*R, 0 \leq R \leq 24$$

and using C as the value in the y index register, an arbitrary location in the video matrix can be accessed. In what follows, the value of B will be calculated from from VIC register 24. Moreover, the user must also note that the matrix of color nybbles has \$0800 as a base address.

1030 data 112,152,192,0,0,0,0,0,0,0,1,1,1,1,1,1
1040 data 2,2,2,2,2,2,2,3,3,3,3,3
```

C. Memory/Register requirements: This routine requires 76 (\$4C) bytes of code including tables. It also expects the row number to be in the x register at JSR time. The accumulator is used but the y register is not.

D. Worst case execution time is 41 (\$29) cycles. (At 1.02 MHz this is 40.2 micro-seconds.)

E. Examples:

1. To change a video matrix entry at ROW 10 and COL 15 to character number 127 and the corresponding color code to 7 (yellow) one can use the following code:

```
LDX #10          ;(ROW #)
LDY #15          ;(COL #)
JSR SETPTR       ;SET UP POINTERS
LDA #127          ;CHR# 127
STA (VPTR),Y      ;STORE 127 @ VM(ROW, COL)
LDA #7            ;
STA (CPTR),Y      ;STORE 7 @ CM(ROW, COL)
```

2. To read the character code at ROW 10 and COL 15, one could use:

```
LDX #10          ;(ROW #)
LDY #15          ;(COL #)
JSR SETPTR       ;SET UP POINTERS
LDA (VPTR),Y      ;LOAD .A WITH VM(ROW, COL)
```

Software Application Note 2002

Authors: Jeff Bruetta and Andy Finkel

Subject: Horizontal Scrolling

Television Standard: NTSC

I. Abstract: This scrolling routine performs all of the functions necessary to smoothly scroll the screen left or right. In one pass, it can scroll any increment from one bit to one byte. The main use of this routine would be for effects in which the landscape move by. Characters and color memory both move.

II. Exposition: The users program should call the routine labeled "SETIRQ". This will set up the routine variables and the raster interrupt routine. Since the speed of the scroll is user definable, the user must store the speed in the variable called "SPEED". This may be done as often as necessary, but if the speed desired is to be constant, once is enough.

SPEED is expressed in two's complement form and the valid ranges are $0 \leq \text{SPEED} \leq 8$ or $-8(\$f8) \leq \text{SPEED} \leq -1(\$ff)$. Therefore, moving $\$f8$ scrolls 8 bits at a time from right to left while $\$08$ scrolls 8 bits at a time from left to right. These numbers reflect the number of bits moved every 1/60th of a second (one screen scan of the raster). This holds true only if the routine labeled "BITMOV" is call at least once every 1/60th of a

second.

Assume that you character rows 3 (\$03) through 12 (\$0C) were to be scrolled, while all other rows were stationary. There is a formula to figure row/rasterline values. The formula is: $\text{CHARACTER ROW} \times 8 + \$2A = \text{TOP RASTER OF THAT ROW}$. In this example, the raster line for the top would be \$42. This number should be placed in the constant that is named "TOP". The same formula should be used for calculating the bottom raster line but, add \$07 to the answer. In this example, that number would be 12 (\$0C). The answer is be \$8A. Since we are scrolling rows 3 (\$03) through 12 (\$0C), there are 10 (\$0A) lines being scrolled. Put this number in "ROWS".

The starting address of the top scroll row is also needed. This number minus 40 (\$28) will give a two byte address. The high byte should be put in "HIBYTS". In this example, this would be an \$04. The low byte is a \$28. This should be put in "LOBYT". The only constant remaining is "HIBYTC". This is the high byte of the top of the color ram area being scrolled. Assuming that the start of screen memory is at 1024 (\$0400), "HIBYTC" would be "HYBYTS" + \$04. Put a \$08 in the "HIBYTC" constant. Once these changes are made, this routine should be ready to use.

A note that should be made is that this routine must be used in the 38 column mode. This is an important point to make if the application note which deals with on screen detection is being used. Also, there are two changes to make in RASTWT if you are using multi-color mode. These changes are commented.

Another point which needs mentioning is a description of the YERPLT routine. This is a routine which must be supplied by the user. What it must do is place characters and/or colors which are

being introduced as new pictures. These character/colors should be put on the screen in the proper column. The proper column is automatically stored in the variable named COLUMN. An example of YERPLT is used in the demonstration program. This routine does not put up new information on the screen, but rather "wraps" information from one side of the screen around to the opposite side of the screen (i.e. puts column 0 into column 39 or puts column 39 into column 0).

Execution Times:

Since the execution times vary dependins on what area of the screen is being scrolled and the speed of the scroll, I have broken the routine into sections.

One pass only	SETIRQ	Always: 78 cycles
Once per frame	BITMOV	Best Case: 34 cycles Worst Case: 61 cycles (Worst case means that RLMOVE or LRMOVE is to be called because character boundary was crossed.)
Every 8th bit move	RLMOVE	Best Case: 1,118 cycles Worst Case: 28,733 cycles
Every 8th bit move	LRMOVE	Best Case: 1,118 cycles Worst Case: 28,733 cycles
Once every 1/60th. sec.	RASTWT	Always: 126 cycles

EXAMPLE

Here is a sample of smooth scrolling. This program will leave text on the top and bottom of the screen stationary. Using a joystick, control the speed and direction of the text in the center.

SOFTWARE APPLICATION

NOTE 3005

Authors: Joe McEnerney and Eric Cotton

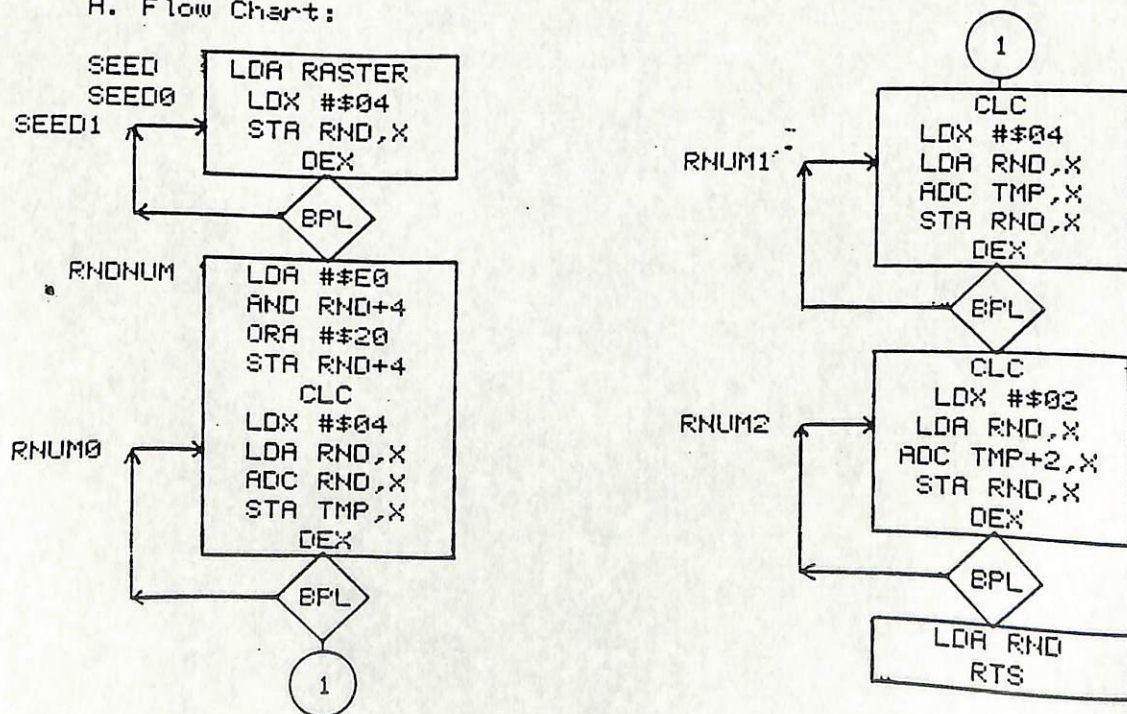

Subject: Random Number Generator

Television Standard: NTSC or PAL

I. Abstract: This subroutine generates psuedo-random numbers by the congruence $x(n+1) = (3 + 2^{17}) * x(n) \text{ mod } (2^{35})$. $x(0)$ can be any non-zero value. The routine will force this seed value to be odd to insure the maximum period. This routine operates in binary and the results will be a 35 bit binary number residing in the most significant 35 bits of a 5 byte field. The period of the sequence is 8,589,934,592 and the most significant byte is most random. A time based seed can be obtained by calling the routine called 'SEED'. The generator is normally seeded once. Subsequent calls to 'RNDNUM' will produce new random values. At RTS time the accumulator will contain the most significant byte.

II. EXPOSITION:

.. 2030 09 95 02 CA 10 F7 A5 02 60
```

3. Data statements (as assembled at \$C000):

```
1000 data 173,18,208,162,4,149,2,202,16,251,169,224,37,6,9,32
1010 data 133,6,24,162,4,181,2,117,2,149,7,202,16,247,24,162
1020 data 4,181,2,117,7,149,2,202,16,247,24,162,2,181,2,117
1030 data 9,149,2,202,16,247,165,2,96
```

C. Memory/Register requirements: The routine requires 57 (\$39) bytes of memory. Also, 10 bytes for variables are needed (preferably on zero page). The routine also requires use of the accumulator and x register.

D. Worst case execution time is 355 (\$163) cycles (346.85 micro-seconds) when initially seeded and 301 (\$12D) cycles (294.08 micro-seconds) each time RNDNUM is called.

E. Limitations: Because the high order byte has the longest period, it is most useful when a random byte is needed.

F. Initialization: This random number generator need only be seeded once. For a time-based seed call SEED; otherwise load the accumulator with an alternate value (0 through 255) and call SEED0.

G. Note: The random number generator on the Sound Interface Device (SID) may be used as an alternative to the routine presented in this Application Note. The SID generator is not adequate for many applications since it will fail the equidistributive test. Further, use of voice 3 may be limited. Refer to the 6581 SID chip specification for more information.

H. Example: The following example demonstrates the use of the random number generator. Its purpose is to simulate throws of a pair of dice. When executed, hitting the F1 function key will roll the dice and display their values on the top-middle of the screen. Pushing the F3 function key will cause a break to the monitor. (Make sure the \$8000 version of VICMON -XVM4.8- is loaded.) Note that the first operation of the program is to seed the program with the 8 LSB's of the raster value.

The starting address of this example is \$C000.

SOFTWARE APPLICATION NOTE 4001

Author : Bill Hindorff & Joe McEnerney

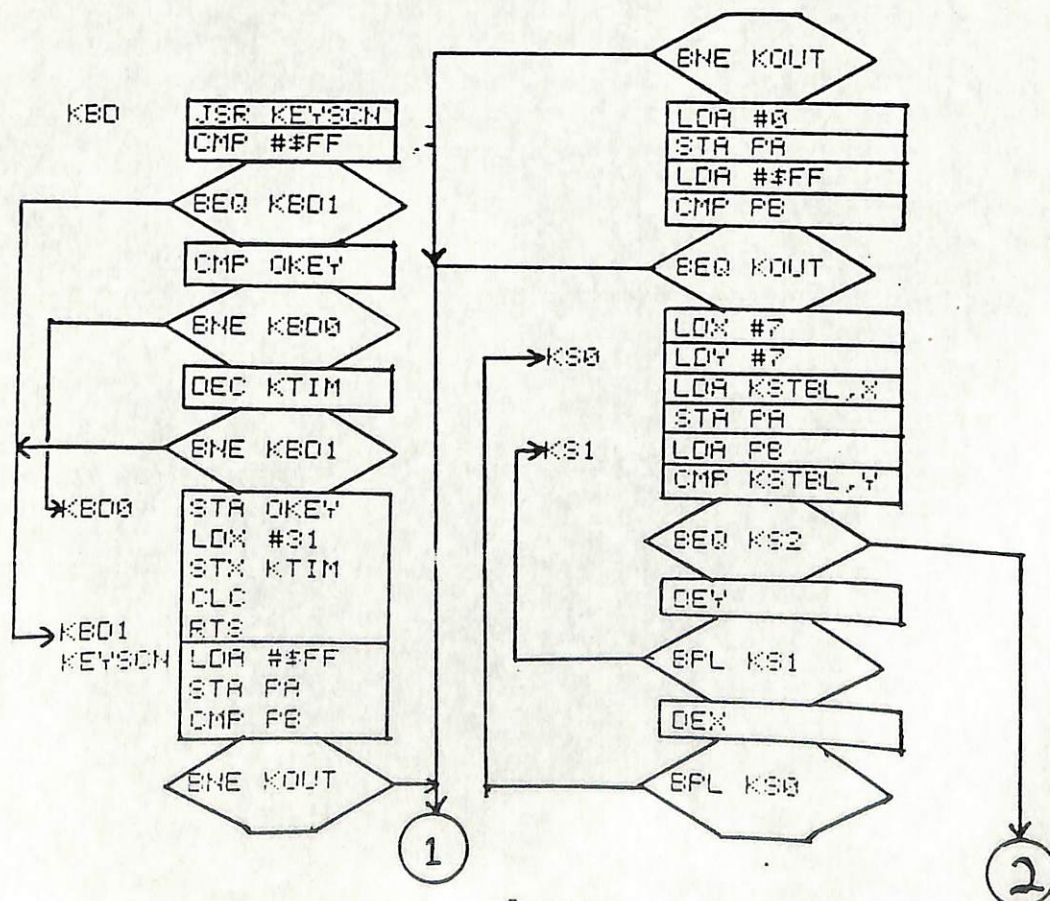

Subject : Keyboard Scanning routine

Television Standard : NTSC or PAL

Abstract : This routine reads and decodes keyboard data from ports A (\$0C00) and B (\$0C01) of CIA #1 (MOS 6526 chip). It is not designed to be called more than once per 1/60th of a second, and as a result, is well suited to an IRQ routine. A key on the matrix which is held down for more than half a second will auto-repeat. Upon return from the subroutine, the accumulator and a memory location defined by the variable OKEY will have been set to the row and column of the current key pressed. The upper four bits contain the row and the lower four bits contain the column. The carry is set if either no new key has been pressed, or a key has not been held down for half a second.

DATA 253,251,247,239,223,191,127

```

d) Memory/Register requirements: This routine requires 94 (\$5E) bytes of memory. It uses the accumulator, X, and Y registers and 3 bytes of storage.

e) Worst case execution time is 1185 cycles (or 1161.30 μ secs on a 1.02 MHz system).

f) Limitations: A valid key has been pressed if and only if the carry is clear upon returning. Otherwise, the data in the accumulator and OKEY should be ignored. The routine can not determine if the keyboard or joystick pair caused a keypress.

g) Prior to using this subroutine, OKEY should be initialized to an \$FF.

h) Example:

This example waits for a valid key to be pressed then displays the row and column of the key pressed.

SOFTWARE APPLICATION NOTE 4002

Author : Bill Hindorff & Joe McEnerney

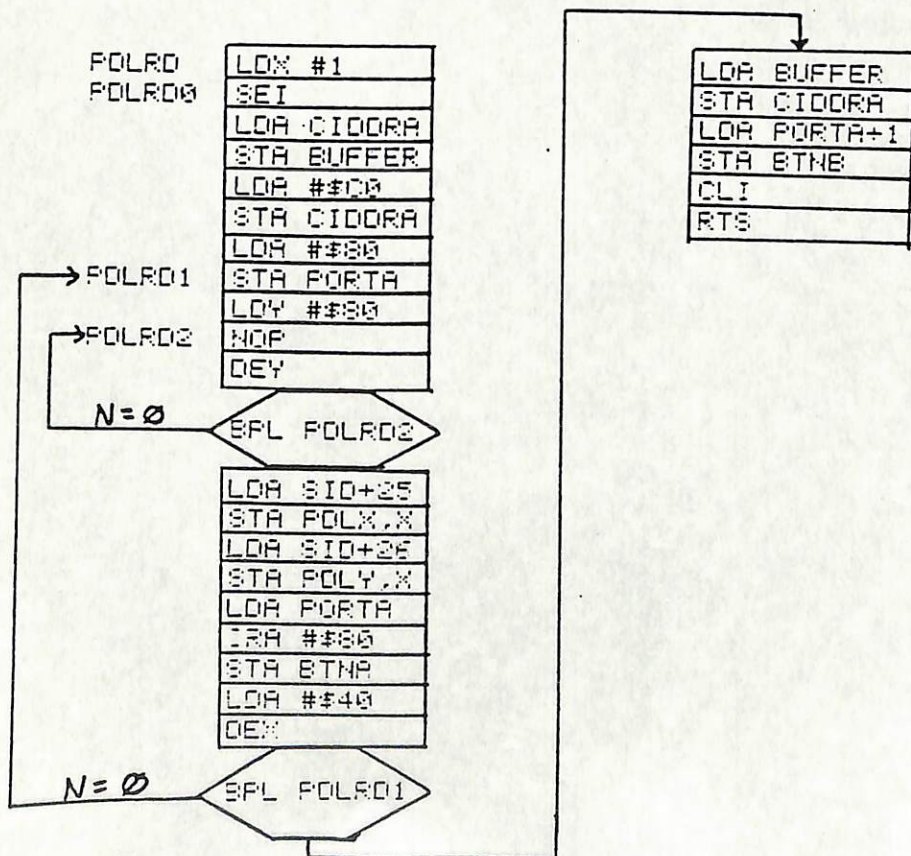

Subject : Analog Joystick/Four Paddle Read

Television Standard : NTSC or PAL

Abstract : This routine reads and decodes the paddle data from the SID (MOS 6581 chip) and reads the fire button data from ports A and B of CIA #1 (MOS 6526 chip). The standard entry point will read all four paddles (equivalent to two analog joysticks) and store the values. It also reads ports A (\$DC00) and B (\$DC01) and stores the values obtained. Bits two (2) and three (3) of \$DC00 and \$DC01 reflect the status of paddle fire buttons attached to ports A and B respectively. A second entry point, which reads paddles attached only to port A, is allowed provided the X register is conditioned to zero before the routine is called.

Exposition :

a) Flow chart

b) Diagrams: The following diagram illustrates the bit patterns associated with paddle fire buttons.

c) Program listing as assembled at \$C000

DATA 169,64,202,16,222,173,0,193,141,2,220,173,1,220,141
DATA 6,193,88,96

```

d) Memory/Register requirements: This routine requires 63 (\$3F) bytes of memory. It uses the accumulator, X, and Y registers and 7 bytes of storage.

e) Worst case execution time is 1907 (\$773) cycles (or 1868.86 µsecs on a 1.02 MHz system).

f) Limitations: This routine will not condition the two bytes which contain paddle fire button data. The button combinations produce data as follows:

BUTTONS PUSHED	HEX VALUE	DECIMAL VALUE
NONE	\$FF	255
PADDOLE X	\$FE	254
PADDOLE Y	\$F7	247
BOTH	\$F3	243

g) Prior to using this subroutine for a single pair of paddles, be sure you have conditioned the X register to a zero

h) Example: The following BASIC program POKES the paddle reading subroutine into memory starting at location 49152 (\$C800). It then calls the subroutine and displays the paddle data on the screen.

```
10 C=12*4096:REM SET PADDLE ROUTINE START

```

SOFTWARE APPLICATION NOTE 4003

Author : Bill Hindorff

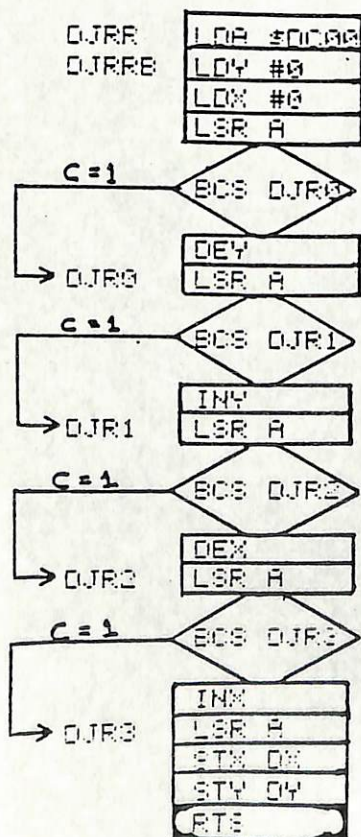

Subject : Digital Joystick Read

Television Standard : NTSC or PAL

Abstract : This routine reads and decodes the joystick/firebutton data as given in the accumulator. The accumulator is assumed to be a value from port A or port B of CIA #1. The routine will set two variables, DX and DY, which represent the two's complement direction vector. I.E. \$FF = -1, \$00 = 0, and \$01 = 1. Upon returning, the carry reflects whether or not the fire button is being pressed. Carry set (c = 1) means the button was not pushed, carry clear (c = 0) means the button has been pushed.

2) Hex Dump:

```
..: 0200 A2 00 A0 00 AD 00 DC 4A B0 01 88 4A B0 01 C8 4A
..: 0210 B0 01 CA 4A B0 01 E8 4A 8E 10 C1 8C 11 C1 60 80
```

3) Data Statements:

```
DATA 162,0,160,0,173,0,220,74,176,1,136,74,176,1,200,74
DATA 176,1,202,74,176,1,232,74,142,16,193,140,17,193,96
```

d) Memory/Register requirements: The routine uses 31 (\$1F) bytes of memory as well as 2 bytes of storage. It also uses the accumulator, X, and Y registers.

e) Worst case execution time is 48 (\$30) cycles (or 47.04 usecs on a 1.02 MHz system).

f) Limitations: This routine assumes that the data direction registers have been properly set to read digital joysticks attached to port A and/or port B. The C64 does initialize the DDR's properly upon power-up to 255 (in \$DC02) and 0 (in \$DC03). If the DDR's are not properly set, then the routine will not yield accurate results.

g) Prior to using this subroutine, be sure that the accumulator holds the joystick reading and that the X and Y registers have been saved. Also see section 4' above.

h) Example: The following BASIC program pokes the joystick subroutine into memory starting at location 49664 (\$C200). It then calls the subroutine and displays the joystick data. The only difference between the example's routine and the assembly listing is that the fire button state has been stored at location \$C112.

SOFTWARE APPLICATION

NOTE 4007

Authors: Joe McEnerney and Eric Cotton

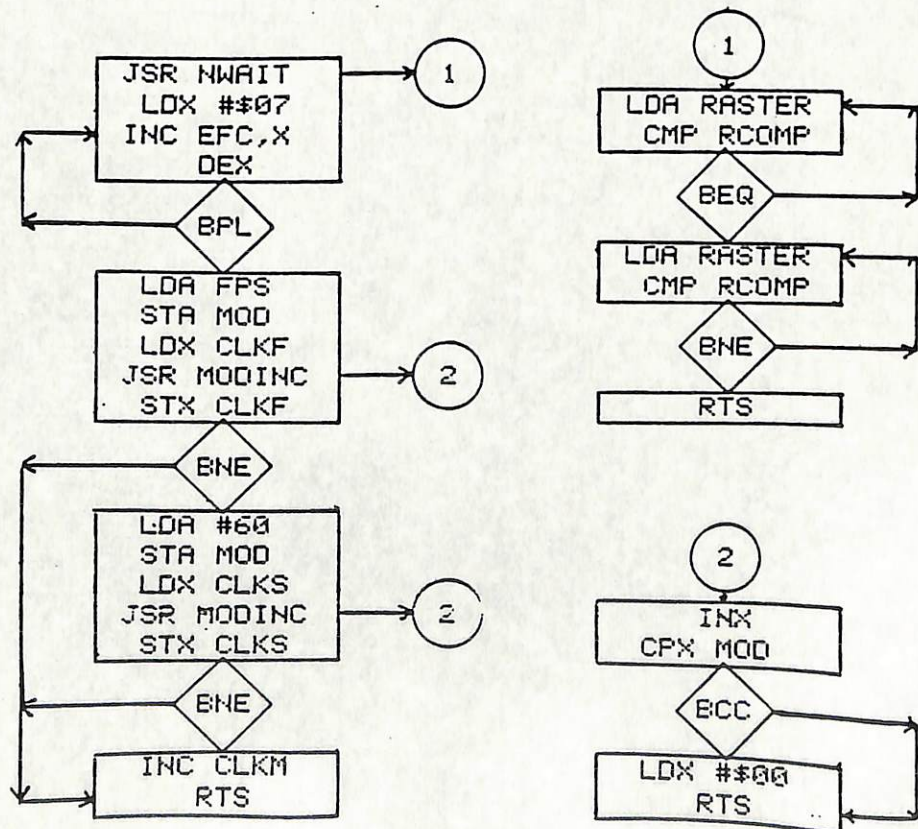

Subject: Clock Functions

Television Standard: NTSC or PAL

I. Abstract: This routine performs various clock functions, the foremost being synchronizing the logic of the calling program to the raster. In addition, it updates a set of eight frame counters, a frame clock, a seconds clock and a minutes clock. CLOCK should be called once per frame.

II. EXPOSITION:

A. Flow Chart:

1030 data 18,208,197,8,240,249,173,18,208,197,8,208,249,96

```

C. Memory/Register requirements: The clock routine and auxiliary subroutines together occupy 62 (\$3E) bytes of memory. The accumulator and the x register are used as well as 14 bytes of zero page for variables. This allows for 8 event frame counters, but more may be added if necessary (see section G below).

D. Worst case execution time is less than 16.91 milli-seconds on a NTSC system, 20.24 milli-seconds on a PAL.

E. Limitations: Because the raster compare is made to the eight least significant bits only, the user is advised to limit raster-compare values to the range 57 through 255 (\$39 through \$ff). This limit assumes the controlling program is to run on both PAL and NTSC television systems. If only operation on NTSC systems is intended, then the range 7 through 255 (\$07 through \$ff) is applicable.

F. Initialization: The clock routine requires that the frames per second value of the television be stored in the variable FPS. This number should be either 50 (for PAL) or 60 for NTSC. See lines 1390 to 1550 of the example for a technique to choose the appropriate television system that the program is running on. The variable RCOMP must be loaded with the raster compare value. Setting RCOMP equal to \$FA will provide the program with the greatest amount

of time to prepare for the next frame. If the minutes/second clock is to be used then CLKF, CLKM, and CLKS should each be initialized with a zero. The event-frame-counters (EFC+0, EFC+1, EFC+2...) should be initialized in accordance with the requirements of the program. These counters are provided so that the user can time events which require many frames to display.

G. CLOCKS

1. Eight event-frame-counters are updated in this routine. CLOCK can be modified to provide more (or fewer) counters by changing the variable declaration in line 1070 of the source listing and the index amount in line 1200.

2. The 6526 Complex Interface Adapter (CIA) -the MAX Machine has one, the Commodore 64 has two- has a Time of Day clock (TOD) which may be used as an alternative to the seconds and minutes clocks provided by the CLOCK routine. See the chip specification for more information.

H. Example: The following example demonstrates one use of the clock routine. When executed, this program will display a solid sprite on the screen as well as its x and y coordinate positions. The user can then use a joystick (put in the port toward the rear of the C 64) to move the sprite to any possible x,y sprite position. The clock routine is used to update the sprite position while the raster is off screen and thus prevent the sprite from flickering.

Notes: a. To fully appreciate how synchronizing a program to the raster can improve appearance, try removing the clock routine from the example. The simplest way to do this is to remove line 1950 from the source listing.

b. Sprite movement in this example is accomplished by UNIMVX and MVSX. For an explanation of these routines refer to Application Note 1001.

c. For an explanation of the joystick routine refer to Application Note 4003.

SOFTWARE APPLICATION
NOTE 4000

AUTHOR : Andy Finkel
SUBJECT : Using the Commodore 64 as a Max Emulator.
TV STANDARD : NTSC or PAL

ABSTRACT

The Commodore 64 can be used to emulate a Commodore Max during software development for the latter machine. This gives several advantages including the use of development tools on the 64, the ability to test the program in RAM (which ends the need to constantly write EPROMs in order to test the program), and the use of the 64 peripherals.

EXPOSITION

A brief review of the way in which MAX programs should be configured is in order:

A game program for the MAX is usually 2K bytes, 4K bytes, or 8K bytes. There is always RAM in the MAX from \$0002 to \$07FF for your program to use. Some programs will require an additional 2K of RAM - this memory would go from \$0800 to \$0FFF. The program must be assembled to run at \$F000 (for the 2K size), \$F000 (for the 4K size) or \$E000 (for the 8K size). The program must include the 3 6510 vectors (NMI, RES, and IRQ) beginning at \$F1FA for the program to operate. Graphics (both characters and sprites) must be located

either in the 4K block beginning at \$F000 or the RAM from \$0002 to \$0FFF.

NOTE: Remember that the ROM graphics block at \$F000 maps down to \$3000 from the point of view of the VIC-II chip.

The object then, is to configure the Commodore 64 to match this specification. The memory configuration of the 64 is controlled by location 1. Placing a \$E5 into location 1 will switch out both BASIC and the KERNAL. The MAX program must replace the KERNAL.

The other problem is to simulate the graphics-mapping effect for the VIC-II chip. This is accomplished by having the program section that goes from \$F000-\$FFFF also loaded at \$2000-\$3FFF.

There is no problem if your program requires the extra 2K of RAM, since the Commodore 64 always has RAM there.

SUMMARY

- 1) Assemble the MAX program at \$E000 for an 8K cartridge program
at \$F000 for a 4K cartridge program
at \$F000 for a 2K cartridge program

Remember to include the interrupt and reset vectors for the 6510 chip at \$FFFA.

- 2) Do an OFFSET load using the HILOADER.C4 program included with the Commodore 64 Assembler Development System- use an offset of 4000. This will offset your program as follows:

MAX ADDRESS	PROGRAM WILL BE LOADED AT
\$E000-\$EFFF	\$2000-\$2FFF
\$F000-\$FFFF	\$3000-\$3FFF

- 3) Now LOAD the MAX.EMU program as execute it as follows:

LOAD "MAX.EMU",8,1
SYS 9*256

Your program will be transfered from \$2000-\$3FFF to \$E000-\$FFFF, the memory will be reconfigured, and execution will begin at the address specified by the RLS vector in your MAX program.

Please note that the max emulator program is completely

relocatable. It can be moved anywhere, if the location occupies conflicts with another development tool. The zero page locations can be can be changed by reassembly.

SOFTWARE APPLICATION

NOTE 4003

Authors: Joe McEnerney and Eric Cotton

Subject: Power On Clear

Television Standard: NTSC or PAL

I. Abstract: The Power On Clear (POC) routine performs many of the setup duties necessary in most programs. Among other functions it will:

1. initialize the microprocessor stack pointer
2. initialize the 6566/67 VIC registers
3. clear the 6581 SID registers
4. determine the television standard
5. set up the I/O ports
6. set up the video and color matrices
7. stop all interrupts from the 6526 CIA
8. set up the sprite pointers
9. set up interrupt structure

All or part of this routine may be used in accordance with the requirements of the user's program. Also, the user may wish to change some of the constants to meet his particular needs.

II. EXPOSITION:

A. Flow Chart: The following chart summarizes the functions of POC and illustrates the order in which they are executed.

disable IRQ'S
clear decimal mode
set up I/O ports
set stack pointer
clear zero page
clear VIC registers
clear SID registers
set up 6510 DDR
initialize VIC registers
determine T.V. standard
clear and color screen
clear timer a control reg.
set up sprite pointers
prepare IRQ's
enable IRQ'S

```

C. Memory/Register requirements: The PDC routine requires 171 (\$AB) bytes of memory. This includes 7 bytes for a VIC register table as well as 7 bytes for lines 2350 through 2370. In addition, 4 bytes are needed for variables, preferably located on zero page. The accumulator and the x and y registers are used.

D. Worst case execution time is less than 1/30 second on a PAL television system, 1/25 second on a PAL.

E. User Notes:

1. Lines 2070 and 2080 of the source listing are optional for programs made to run on the MAX Machine alone. CIA+\$E is cleared on power-up. Such is not the case on the Commodore 64, so if CIA interrupts are to be disabled, this register must be set to 0 by the program.
2. The PDC routine has been organized into sections so that the user can easily modify the routine to meet the needs of his particular program. In the source listing each section is headed by a comment (describing the function) surrounded by asterisks. If a section is not needed it can be deleted without affecting the others. However, the x register should be preserved when either "SET UP I/O PORTS" or "SET STACK POINTER" are deleted.
3. The constants and the VIC register table (VTBL) are given sample values and can be changed in accordance with the user program.
4. An indirect jump in line 2360 was provided to accommodate multiple IRQ routines.
